Wickman Machine Tool, Inc.
1521 Imhoff Drive, Unit F
Lake in the Hills, IL 60156
Tel: 847 458 6400 Fax: 847 458 6401

We at Wickman Machine Tool are always working on improving our customer service. We want you, our customer, to feel confident that we are doing everything that we can to give you the best service possible.

Firstly, in order to improve our service; we need to improve the communication system between us and our customers. We have listed below a number of important contacts for you to reach the people you need to speak to directly with ease.

MACHINE INQUIRIES / TECHNICAL

Jeremy Rose – President

Mobile: 847 736 6629
Office: 847 458 6400 Ext 208
Fax: 847 458 6401
E-mail: j.rose@wickman-usa.com

SPARES / GENERAL INQUIRIES

Reyna Rios – Spares/General Inquiries

Office: 847 458 6400 Ext 207
Fax: 847 458 6401
E-mail: r.rios@wickman-usa.com

TECHNICAL SUPPORT

Scott Andersen – Technical Engineer
- Spares / General Inquiries

Office: 847 458 6400 Ext 204
Mobile: 847 217 6664
Fax: 847 458 6401
E-mail: engineer@wickman-usa.com

SALES / MARKETING

Alison Rose – Office Manager / Accounts
- Spares / General Inquiries

Office: 847 458 6400 Ext 201
Mobile: 847 526 6664
Fax: 847 458 6401
E-mail: a.rose@wickman-usa.com

ACCOUNTING

Katherine Furnas – Financial Controller

Office: 847 458 6400 Ext 206
Fax: 847 458 6401
E-mail: accounts@wickman-usa.com

Customer service is our priority. We want to build strong relationships with all of you. Therefore, if you ever want to call up to negotiate availability, quality, price, turnaround times, responsiveness to your inquiries or any other factor that will affect your decision to buy from us, please feel free to do so and we will do whatever it takes to try and meet your requirements.

Kind regards

The Wickman Team

TANGI-FLOW PRODUCTS LTD

Webster WB Bennett

Your attention please !

The references at the foot of each page show that this manual was prepared in 1988.

Unfortunately it was never completed, probably due to the compiler being made redundant as a result of the drastic reductions in manpower which the company was forced to make during that difficult time.

The 'masters' were found in the company archives in February 2005. The manual was found to be complete and ready for printing apart from Section Five: Parts Lists and Machine Drawings. Whilst the lists of parts had been done, much of the artwork (with index numbers) was missing.

Unfortunately we do not have the resources at present to prepare new artwork so we have inserted at the appropriate point a scaled-down print of the appropriate drawing on which all of the relevant part numbers are shown. Where we have done this, the list of parts has been marked 'REFER TO DRAWING SHOWING ALL PART NUMBERS'.

We trust that this will be acceptable and we are pleased that at last we now have a manual dedicated to the 1.3/4" 8-Spindle machine. Hitherto we could only offer the 2.5/8" 6-Spindle manual with a few inserted pages for the 1.3/4"-8.

TABLE OF CONTENTS

Wickman Bennett Machine Tool Co. Ltd., operate a policy of continual improvement. We therefore reserve the right to change the specifications and illustrations without notice.

PREFACE

This Manual provides the basic information and instructions that are necessary for the maintenance/servicing of the Wickman 1.3/4"-8, 1.3/4"-8S (arranged for spindle stopping) and the 50mm-8 Spindle Bar Automatic Lathes with relay logic control.

The contents will familiarize the reader with the machine construction specifications, installation procedure, safety at work and all the relevant aspects of the machine.

The manual should be read thoroughly. It will enable the Engineer to gain the knowledge required for the correct and efficient servicing of the machine.

An Operator's Handbook is also available for the 1.3/4"-8, 1.3/4"-8S and 50mm-8 machines.

HEALTH AND SAFETY

Health and Safety at Work Act, 1974 - U.K. users only.

In accordance with the requirements of the Health and Safety at Work Act 1974, this manual embodies the necessary information to ensure that the machine tool can be maintained properly and with safety. It should be clearly understood that the engineer must be properly trained, have the required skills and be authorised to maintain the machine.

If it should arise that the person authorised to maintain the machine is undergoing training, he must be under the close supervision of another skilled and authorised person.

Adequate information is provided to enable the machine to be serviced and maintained in a satisfactory condition by engineers and electricians who have the necessary skills and authority. We recommend that a 'Permit to Work' system as detailed in BS5304; 1988 entitled "Safety of Machinery", should be operated.

It is important that the various statutory regulations which are applicable, eg, 'The Protection of Eyes Regulations' are complied with.

Operating Discipline

(I) A clean, neat and well ordered machine and working area is the first essential of safety at work.

(II) All guards, cover plates, cabinet doors and the tooling area guards must be in place or closed before any production run commences.

(III) Never leave articles lying on any working surface where there is a danger that they may be dislodged by: any moving part of the machine, vibration, etc.

(IV) Never wear rings, watches, neck-ties or loose-sleeved clothing when working on the machine.

(V) Never operate the machine in excess of its rated capacity.

(VI) Know where the EMERGENCY STOP BUTTON is.

(VII) Never reach across a moving or rotating part of the machine

(VIII) Never enter the tooling area or any other working part of the machine when the machine is running on production.

(IX) When tool setting, changing tools or making adjustments, never enter the tooling area until the machine has been shut down.

(X) When carrying out maintenance work, never enter any part of the machine, either mechanical or electrical, until the machine has been shut down and the isolator on the electrical control panel is in its "off" position, disconnecting the power supply.

(XI) When working with lubrication oils and cutting oils of the soluble and straight cutting oil types, cleanliness is essential. Precautions must be taken to avoid all unnecessary contact with oil by ensuring that the machine's protective devices against coolant and oil spray are correctly closed and that protective clothing is worn. Never wear oil soaked clothes or place oily rags or tooling in the pockets of wearing apparel. Always was oil from the body as soon as possible after contamination.

The Safe Operation Of Work Holding Devices

Collet equipment and collet operating mechanisms must always be kept in first class condition, in order to ensure that the bar is securely gripped to withstand all the applied cutting forces. Tooling area guards must always be closed when the machine is in the "run" condition.

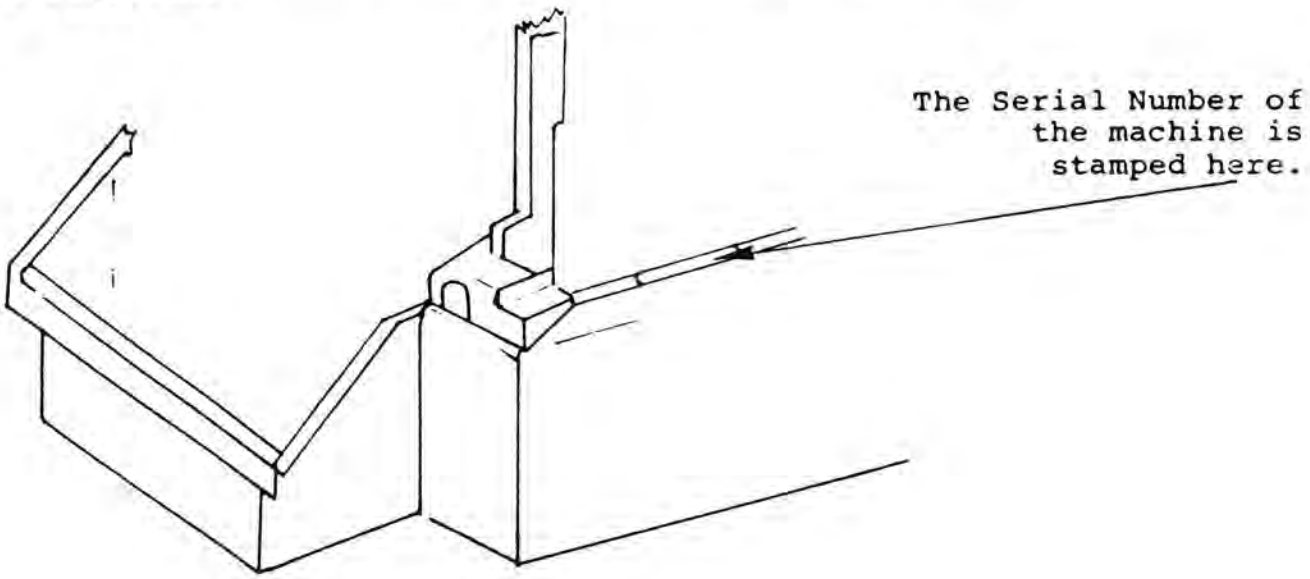
MACHINE SERIAL / INSPECTION NUMBER

In the event that queries arise with regard to the maintenance of the machine, it is important to note the following details which would need to be given to Wickman Bennett in all correspondence, ie:

Machine Inspection/Serial number. Machine size and Model.

The machine Inspection/Serial Number must always be quoted and is stamped on the machined-rim of the Tray of the machine, on the left hand side, close to the Operators position. Additionally the number is also engraved on the machine Manufacturing Plate (WSP500) which is affixed to the Main Drive Housing casting at the rear of the machine.

Reference to this number will facilitate any service that may be required.



DETAILED CONTENTS LIST

SECTION ONE - INSTALLATION

1.1 Lifting the Machine

When planning the siting of a machine consider the space required for chip removal, bar loading and servicing, i.e. centre-shaft removal. Dimensions of suitable lifting bars for use with a crane are shown on the Foundation Drawing Fig.1.1.Slings must not lie against the machine during hoisting. Examine the position of the sling with tension on the rope before the full weight of the machine is lifted.

Where a crane is not available, the machine may be moved by "wedge" truck or rollers and continuous machined surfaces are provided on the underside of the machine tray to facilitate the operation. Rollers must be longer than the machine tray width.

Careful handling of the new machine will ensure accurate alignment.

1.2 Siting and Foundations

The machine should be installed on a level and stable foundation in order to ensure accurate alignment is maintained. A concrete base is recommended. It provides the most suitable foundation because of its stability and because it is less prone to distortion when laid down in adverse soil conditions.

The actual depth of concrete base must be determined to suit the prevailing soil conditions, which must be capable of supporting the machine, its ancillary equipment, its tooling and the concrete base itself.

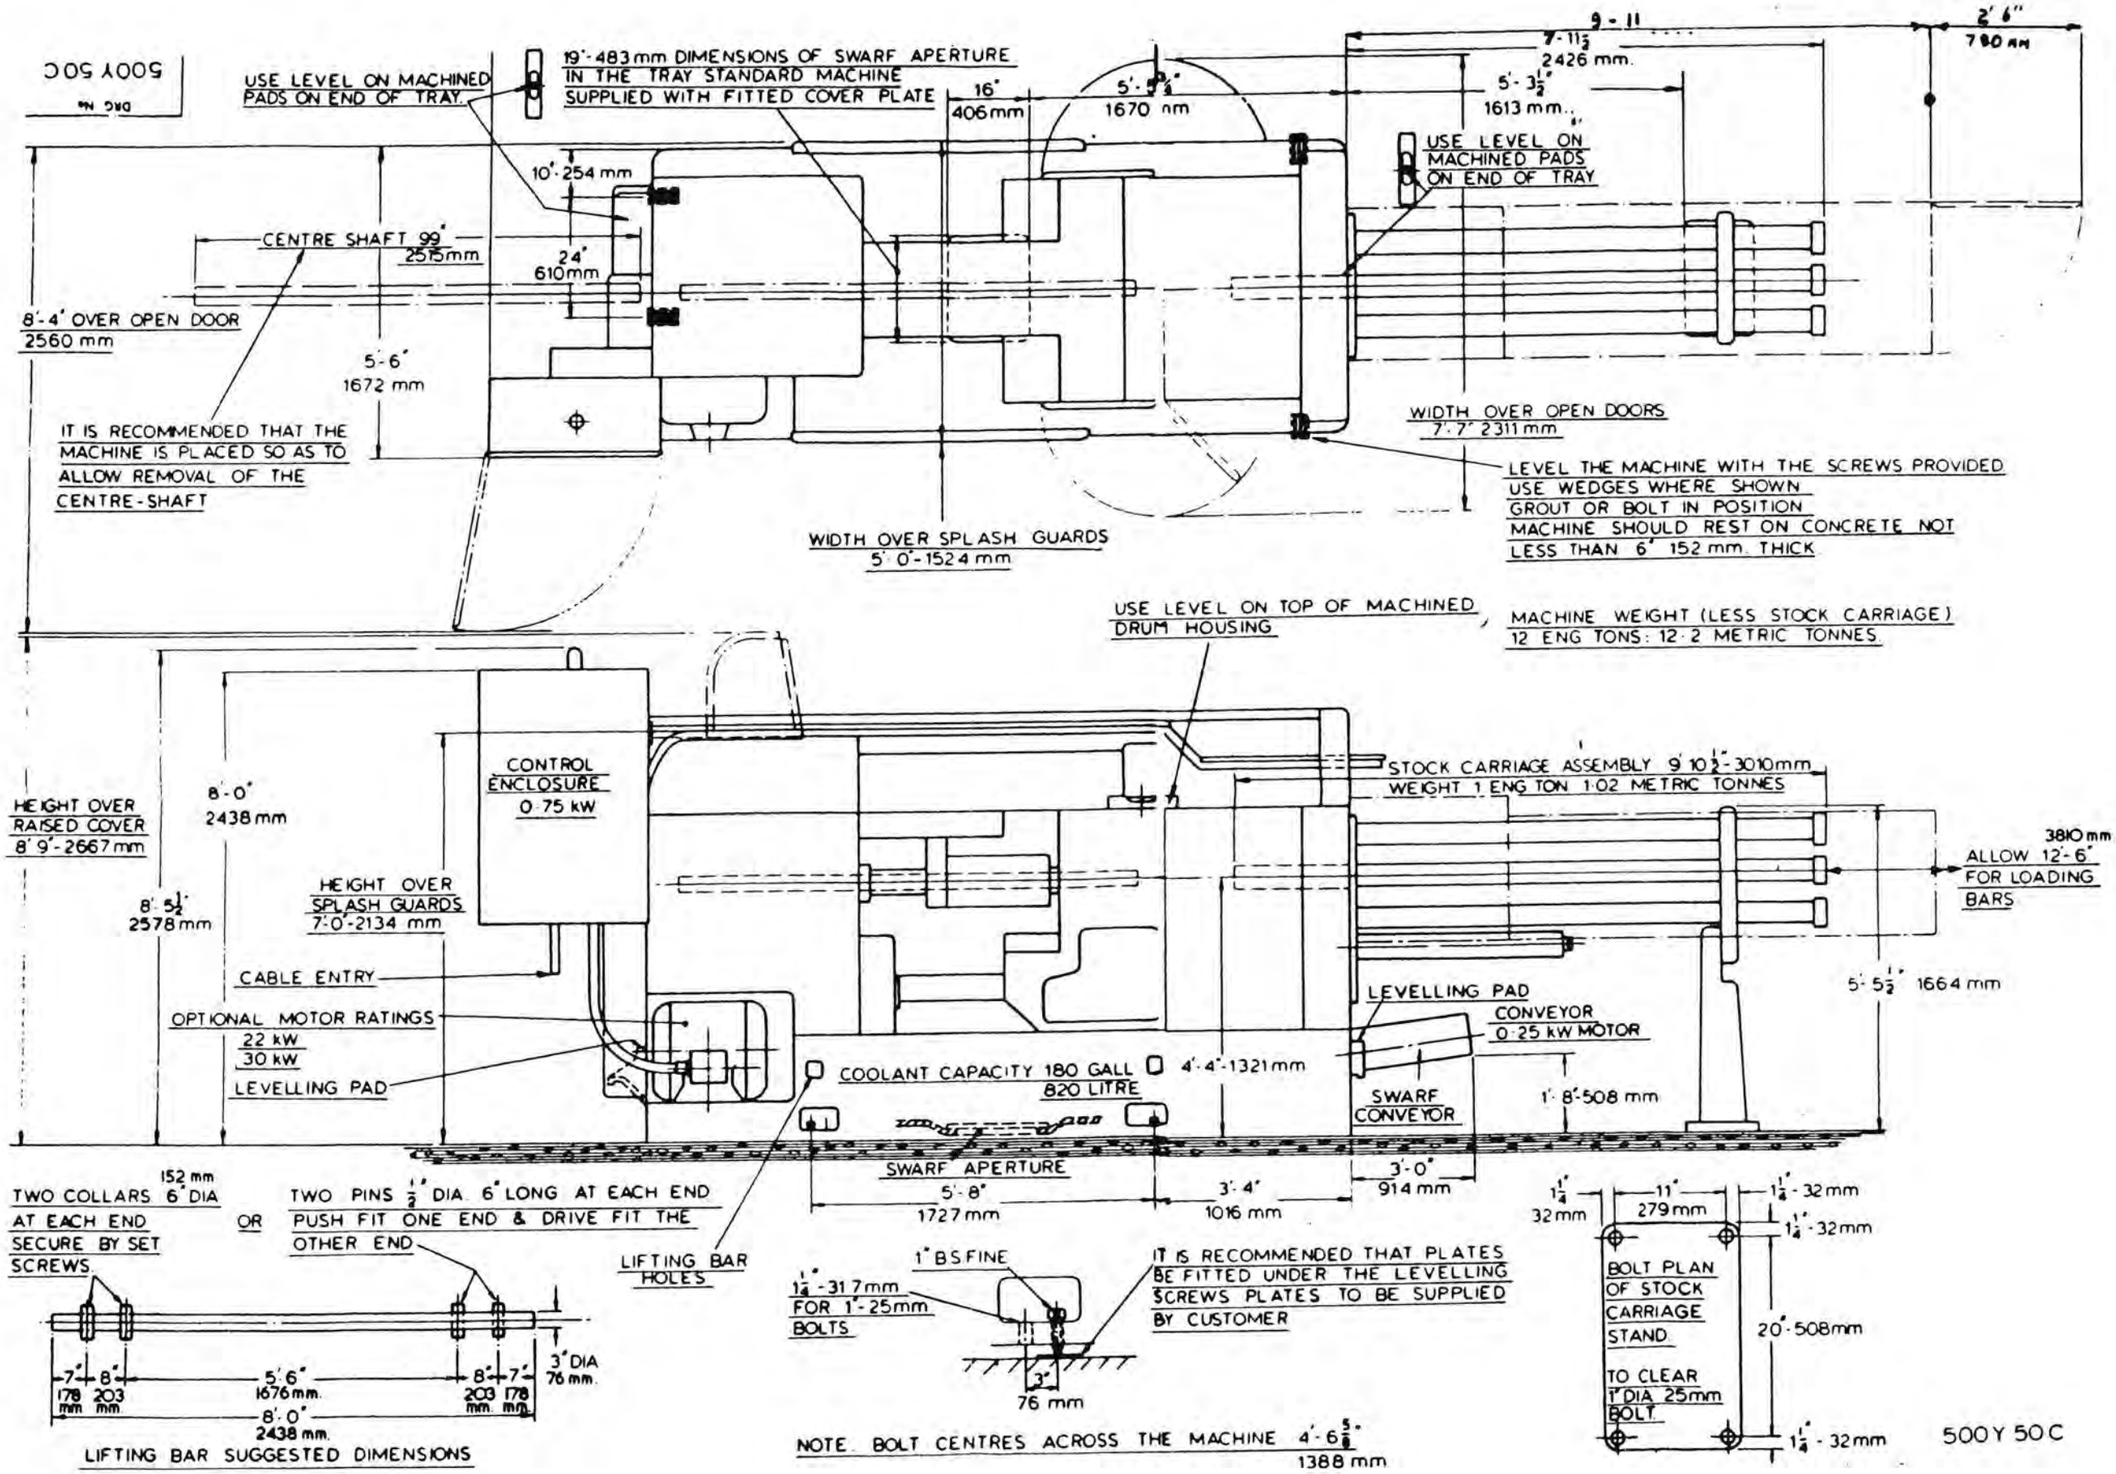
The soil should be consolidated with crushed rock, pebbles and stones.

With the machine in position on the factory floor, level using the jacking screws provided in the machine tray. It is recommended that steel plates be placed between the floor and the screws. Longitudinal and lateral alignment levels can be checked with a precision level on the facings provided at both ends of the machine tray and on top of the spindle drum housing, see Foundation Drawing Fig.1.1. Wedges should be placed at the positions shown.

Foundation bolt holes are also provided for use where required, bolts to be embedded in the floor approximately 5in (125mm).

Where not bolted-down, machines can be grouted or cemented by any shop approved method.

Fig.1.1 Foundation Drawing



SECTION TWO - LUBRICATION CHARTS AND SPECIFICATIONS

2.1 General Description

The lubrication system has two separate parts with the two plunger pumps contained in the same unit and chain driven from the constant speed shaft. Access to the unit is through a cover on the lower face of the motor end of the main drive housing.

One side of the pump raises oil from the main drive housing sump and passes it through the lower Purolator filter to distributors which supply all points in the main drive housing. The circuit contains a pressure relief valve set at 10-15lbs/square inch (0.703-1.055kg/square cm), the excess oil being fed to the upper camshaft oil bath. The bath supplies a number of drip points, and should be kept clean of dirt and grease. A strainer box fitted to the pump intake must not be allowed to become choked. Examine twice a year and clean the sump if necessary. Check the oil level in the sump through a sight glass situated in the front of the main drive housing and fill at regular intervals.

The other side of the pump unit draws oil from the tank in the beam through the upper Purolator filter and passes it to sight feed headers for the spindles and to distributors for drum housing and cross slide feeds. The circuit contains a pressure relief valve set at 10-15 lbs/square inch (0.703-1.055 kg/square cm.) and contained in a block. When a "Flush" button in the block is pressed, the relief valve is blocked and a surge of oil is passed to the spindles and drum housing feeds. The "Flush" button should be pressed daily on machine start up.

Oil in the drum housing should be maintained to the level indicated on the rear inside face of the drum housing. Keep clean of grease and soluble coolant contamination.

A priming plug is provided on the Purolator housing for filling or for releasing air locks. Purolator handles should be turned clockwise two or three turns each day to clear the element of foreign matter. The units should be removed twice a year and the element cleaned with paraffin and a soft brush. Use a solvent on gummy deposits.

A Summary of Lubricants, fig. 2.1 specifies the I.S.O. standard for all the lubricants used on the machines.

Fill all grease nipples with grease, etc., as indicated on the chart fig. 2.2. Use ball bearing grease sparingly in the spindle nose labyrinth seal nipples.

Concerning Lubrication

(a) Check all oil levels in tanks and sumps. They must not fall below the levels indicated.
(b) Frequent checks of the spindle sight-feeds are necessary; also check that the main drive oil is circulating.
(c) Turn Purolator filters daily: apply oil gun to all nipples and oil parts not served by the automatic system.

2.1 Summary of Lubricants

Wickman Oil Grade	1	2	3	4	5
Application	Light Spindle Oil	Air Line Lubrication for Cold Climates	Air Line Lubrication for Warm Climates	Centralised Lube. Air Line Lub'e Hyd. syst. Gen.Lub'e for Cold Climates	General Lubrication Centralised System for Warm Climates

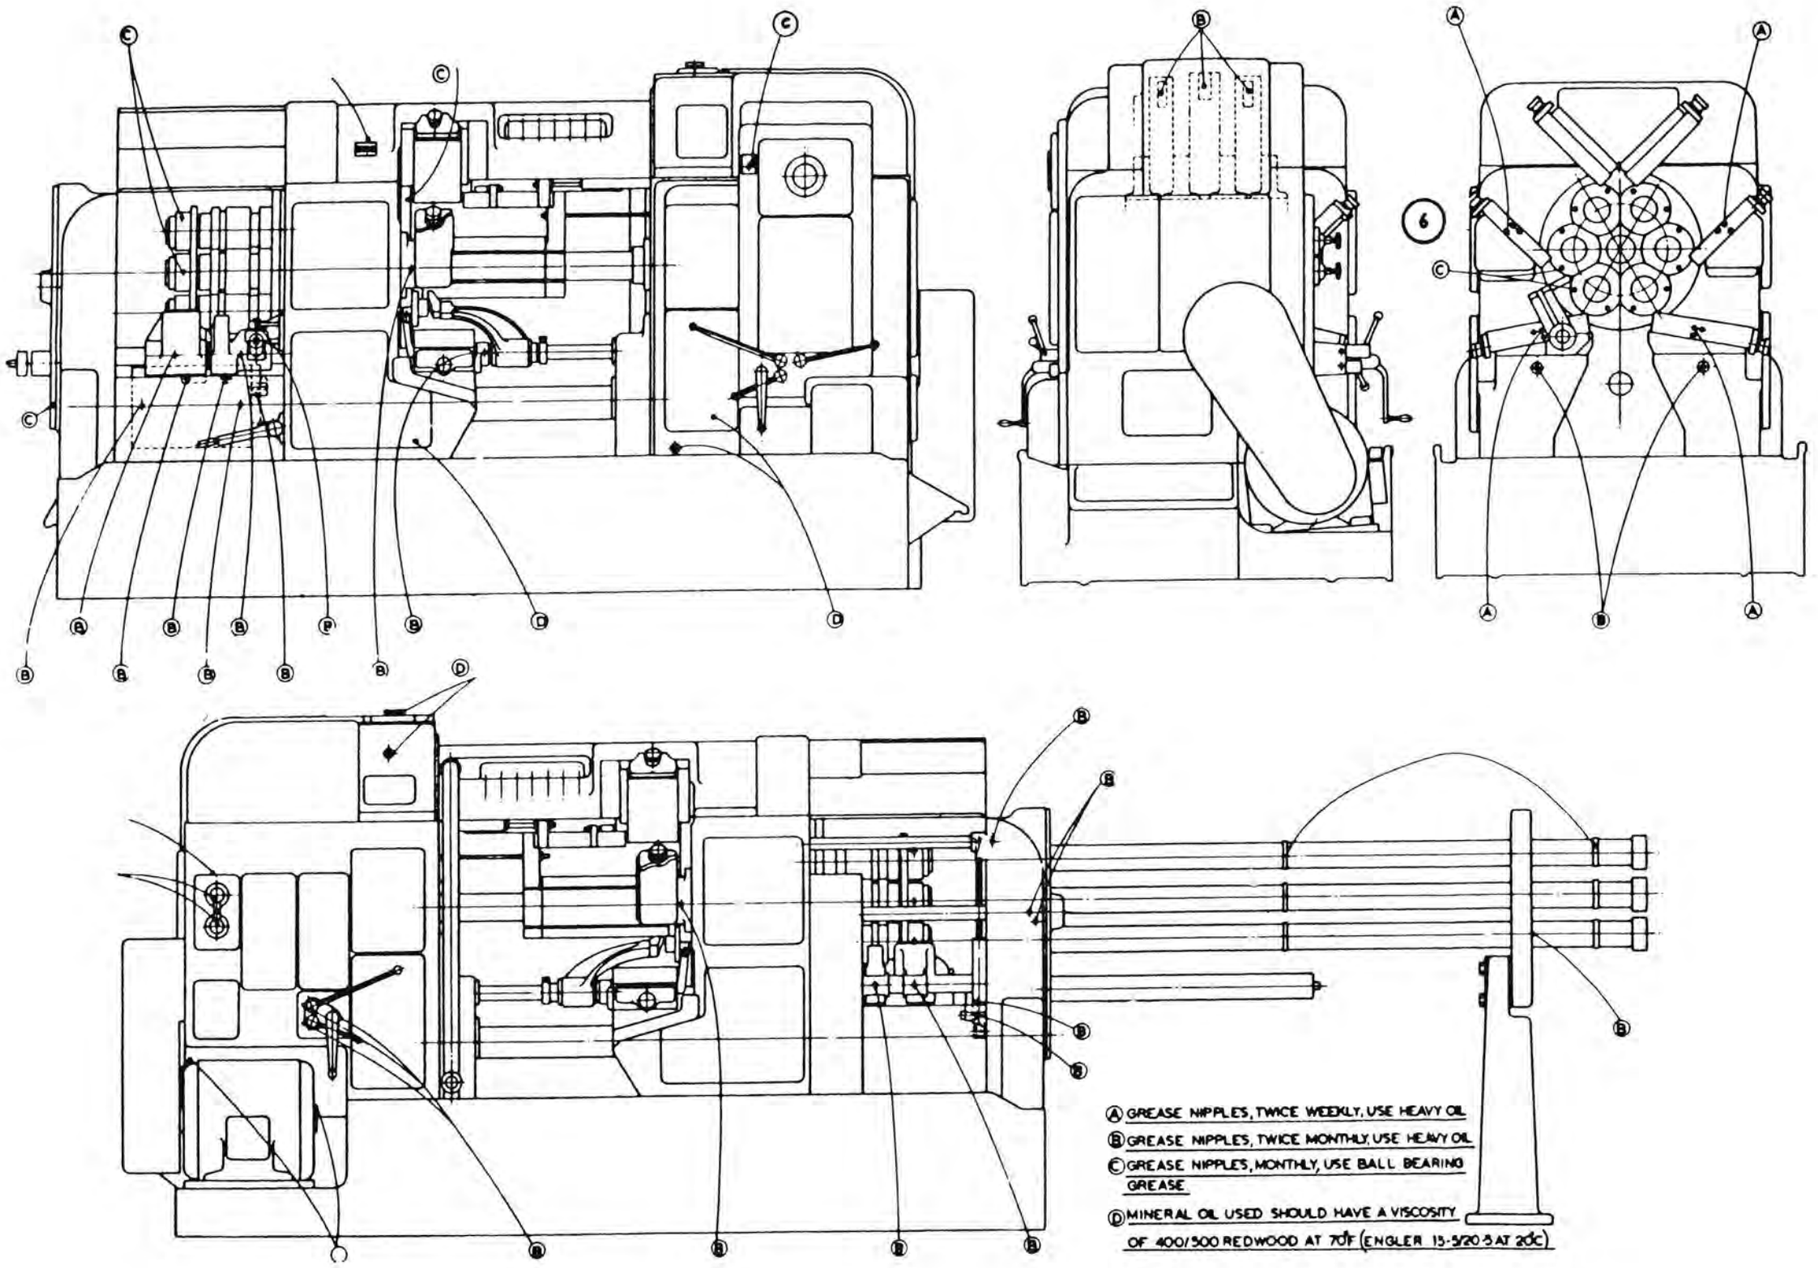
REMARKS:

For Slideways Grade 5 is suitable for use with oil-base coolants and Grade 7 for use with water-base coolants.

* Re: Cosmolube No. 4: Use sparingly and only in nose cap seals.

2.2 Lubrication Chart 1.3/4"-8, 1.3/4"-8S and 50mm-8



SECTION THREE - PREVENTATIVE MAINTENANCE SCHEDULE

3.1 1000 Hour Procedures

Work Schedule to be carried out after 200, 1,000, 2,000, 3,000 hours running, at 1,000 hour intervals thereafter.

Cross Slide Felt Wipers & Aprons:	Inspect and check for damage. Remove swarf particles.
Change Gear Securing Nuts:	Check tightness.
Attachments and Tooling Equipment Securing Nuts:	Check tightness.
Chasing Attachment Drive (if fitted):	Inspect drive chain, check tension, Remove covers and check lubrication. Push back gaiter covers on universal joints and inspect.
Feed Drive - Brake Clutch: Feed - Fast Clutch: Threading: Drive Clutch:	Inspect and check adjustment (see handbook and machine plate). Check drive chain tension
Collet Operating Shoe: Bar Feed Shoe	Inspect for correct alignment and lubrication. (Renew when worn).
Eight Collet Operating Sleeves:	Inspect for correct alignment and movement to avoid overheating.
Bar Feed Mechanism:	Check adjustment.
Bar Feed Mechanism Aligning Ring:	Inspect for alignment.
Cyclic System:	Inspect for leakage caused by loose connections and damaged tubing.
Upper Camshaft:	Check tightness of bolts on coupling between wormwheel and shaft.
Main Block Positive Stop:	Check for excessive pressure.
Independent Slides Positive Stop:	Check for excessive pressure.
Cross Slide Positive Stops:	Check for excessive pressure.
Drum Housing: Main Drive Housing:	Clean lubricating oil sumps.
Coolant System:	Clean tray, taps, pipes and ducts (including manifolds).
Bar Feed Tube Assemblies:	Remove and thoroughly clean. Inspect Feeders.
Collet Tubes, Collets:	Remove and thoroughly clean. Inspect Collets.

Spindle Bore and Collet Seating:	Clean. Inspect collet keys for excessive wear.
Longitudinal Slides:	Pull quadrants back, push forward to check free movement. Adjust gib strip if required.
Spindle Speed and Feed Change Gears:	Inspect lubrication.
Main Drive Housing:	All chain drives, check adjustment and sprocket alignments.
All Cams and Cam Rollers:	Inspect for excessive wear, oil, rollers and pins.
Spindle Drum:	Check end float (see handbook).

3.2 2000 Hour Procedures

Work Schedule to be carried out after 200, 2,000, 4,000 hours running, at 2,000 hour intervals thereafter.

Intake Strainer for Pump on Continuous Lubrication System:	Inspect and Clean.
Interlube Cyclic Metered Lubrication System if fitted:	Check frequency of operation.
Main Drive Belts:	Remove cover, check belt tension and inspect for excessive wear.
Handwind Interlock System:	Inspect and check (see handbook).
Bar Feed Spring:	Check setting.
Control Panel Wire Connections:	Check for tightness.
Control Panel:	Hand operate contactors and relays, ensure free action.
'PUROLATOR' Metal Edge Filter:	Remove, clean filter and case, refit.
'PUROLATOR' "Micronic" Cartridge Filter:	Remove bowl, renew cartridge.
Upper and Intermediate Cross Slides:	Strip, Clean, refit and adjust gib strip.
4th & 5th Station Longitudinal Slides:	Strip, Clean, refit and adjust gib strip.
Chasing Attachment (if fitted):	Strip, Clean, inspect for wear, refit.
Stock Carriage:	Remove springs, clean, regrease, renew as necessary.
Feed Tube: Steady Bushes:	Examine and renew if worn.
Spindles, Collet Operating Toggles:	Strip and examine for wear. (Renew in matched pairs).
Pulley Shaft:	Check for oil leak adjacent to pulley, and renew oil seal if necessary.
Spindles:	Remove collet operating sleeve, examine internal form. Check for correct movement.
Conveyor:	Remove from machine and clean thoroughly. Examine for damage, adjust and refit as necessary.
Spindle Drum:	Check indexing, measure over index. (see handbook).

Drum Locking:	Check setting (see handbook).
Drum Latch:	Check setting, inspect for excessive wear.
Interlube Cyclic Metered Lubrication if fitted:	Drain and clean reservoir.
Centre Block:	Drain and flush. Clean Strainer on guide block. Adjust gib strip if required. Do not over-tighten.
Attachments:	Strip attachment slides, clean, refit and adjust. Inspect, replace worn items. Gears, bearings, splined shafts, clutch parts etc.
Switches:	Check setting, ensure free action, inspect for mechanical damage, check securing screws.
Flexible Electrical Conduits:	Inspect for damage.
Lower Cross Slides:	Strip, clean, refit and adjust gib strip. Replace aprons and felt if worn.
Conveyor Drive Motor Bearings:	See manufacturer's Service Sheets or follow a known procedure for low power motor maintenance.
Upper Camshaft Housing:	Check oil supply to drip tray and outlets.

3.3 4000 Hour Procedures

Work Schedule to be carried out after 4,000 and 8,000 hours running, at 4,000 hour intervals thereafter.

Coolant Pump (Gear Type Only):	Strip and Clean, examine gears, shafts and gland. Renew as required. Refit.
Continuous Lubrication System:	Remove and strip pump, clean and examine for wear. Renew as required. Refit.
Main Drive Housing:	Examine lower and upper camshaft. Worm and Wormwheel. Drives for wear. Replace worn gears.
Spindle Drum, Spindle: Drive Gears:	Examine for wear. Renew if worn.
Cross Slides, Upper and Intermediate:	Replace return springs.
All Chain Drives:	Renew worn chains.
Drum Locking:	Renew Cam Roller and Pin if necessary. Examine Cam and Renew if worn.
Bar Stop Mechanism:	Strip Covers and examine cams, rollers and pins. Replace if worn.
Spindle Assembly:	Remove feed tube assemblies and examine. Replace worn bearings. Remove spindle nose caps, examine piston ring seals, replace if worn.

3.4 12000 Hour Procedures

Work Schedule to be carried out after 12,000 hours running.

Longitudinal Motion:	Examine bushes, and pins, replace as necessary.
Camshafts:	Examine for worn keys and keyways.
Cross Slide Operation:	Dismantle front and rear cam levers and renew bushes. Remove links and cross slide levers and renew bushes and pins and worn shafts.
Main Drive Housing:	Examine initial drive shafts (3). Replace if worn.
Drum Housing & Drum:	Withdraw spindle drum, examine front bearing area on drum & in housing for excessive wear and damage. (Consult Wickman Engineer). Examine drum seal, replace if worn.

4.1 Spindle Speed Drive

The initial machine drive described below covers that part of the drive from the motor to the spindles and indicates where the drive is taken off for further reduction for the feed and the fast motion drive. This is described in section 4.10. The motor, fig.4.1 is mounted on a platform pivoted on the tray and situated at the rear of the main drive housing.

The drive to a constant speed pulley shaft in the main drive housing is by vee belts. To adjust the belt tension the motor platform is raised or lowered by means of two adjusting bolts. Fig.4.1 also shows the direction of rotation of the pulleys.

The constant speed pulley shaft drives the "second" shaft through the range change gears, providing an initial high and low speed range. These gears have a neutral position to disconnect the drive for safety purposes when checking motor rotation.

The drive from the "second" shaft is transmitted by spindle speed pick off gears to the centre shaft. A list of gears is given on fig. 4.2. The centre shaft extends along the main drive housing through the hollow centre guide between the main drive and spindle drum housings and through the centre of the spindle drum to a gear on the rear face of the spindle drum.

Access to the speed pick off gears is at the motor end of the main drive housing. Gear changing is described in the Operators Handbook. Standard attachments are driven from the centre shaft to keep a direct speed relationship with the spindle. The gears and the chain wheels required are supplied fitted. The initial drive for the feed gearing is taken from the centre shaft, so that tool feed for each spindle revolution remains constant with any change of spindle speed, and the overall cycle time will vary with spindle speed changes.

Drives requiring constant speed are taken from the constant speed pulley shaft. These are the fast motion drive, coolant pump drive and the lubrication oil pump drive. All the chain drives and the position of the chain wheels can be seen on fig.4.2. All the chain drives, with the exception of the oil pump drive, are provided with jockey sprockets to tension the chains. The oil pump is mounted on a swinging bracket and chain tension is adjusted by moving this bracket. The chain drives are illustrated with directions for adjustment on fig.4.3

Do not overtighten chains. Correct adjustment should allow the middle of the longer run of any one chain to be moved sideways a minimum of 3/4in (19mm).

4.2 Spindle Drum

The drive from the motor was described to the point where the centre shaft passes through the hollow centre guide to the spindle drum.

Fig.4.5 illustrates this end of the centre shaft, with the spindle drive gear keyed to it and the driven gears mounted directly on each work spindle.

The spindle gears on the 1.3/4"-8 spindle machine are alternately staggered. Spindles 1,3,5 and 7 being arranged with their gears in the inside position. On the 1.3/4"-8S (spindle stopper) and the 50mm-8 machines, the spindle gears are not staggered.

The spindle drum carries the work spindles and the centre guide on which the main tool block slides. This arrangement ensures consistant alignment of the work spindles with the main tool block. The end thrust of the tools upon the spindle drum is taken by the stop ring secured to the front of the spindle drum. This stop ring also carries stop screws which are adjustable dead stops for the innermost position of the cross slides, giving independent setting between each cross slide and spindle in each indexed station.

Hardened steel thrust pads are fitted in the rear flange of the spindle drum to eliminate end float and are ajusted by screws and locknuts. These should be set with no clearance between the pad and the drum housing face when drum is cold.

The drum is supported at both ends in machined diameters in the drum housing. A gear on the rear (bar feed end) of the drum, is driven through a gear train by the Geneva gear, and relays the motion of the Geneva mechanism to the drum to index the drum through 45 degrees. A further gear is taken from the drum indexing gear to drive the indexing of the stock carriage. See fig.4.6.

4.3 Workspindles for the 1.3/4"-8 Spindle Machine

The work spindles are supported at the front in a set of extra precision bearings comprising a parallel roller bearing nearest to the spindlenose and a pair of preloaded angular contact bearings. An extra precision roller bearing supports the rear of the spindle.

The front bearings are protected against the ingress of coolant and swarf by a piston ring seal and labyrinth and by a coolant thrower mounted on the spindle nose. The front bearing end cap iis provided with a grease nipple so that the seal assembly can be filled with grease to exclude foreign matter. Inspection of the seal assembly can be made by removing the coolant thrower and the end cap.

The front and rear bearings are lubricated in the 5th and 6th stations by oil from a pressure header on the beam above the drum housing. Slight drip feeds mounted on the beam are provided for checking the flow. Spacing rings on the spindle assembly retain the lubricant to a suitable level and drilled passages in the drum allow internal oil flow around the front bearing assembly.

4.4 Front Bearing End Float, Collets and Collet Adjustment and Feed Tube Removal

The Timken taper roller bearings are adjusted by a slotted lock nut accessible by removing the front upper cover on the drum housing. The slotted lock nut is split and clamped by a cap screw. The cap screw should be kept lightly clamped whilst adjusting the bearings. The following procedure is recommended when checking and adjusting:-

a) Check end float with a clock indicator (preferably a magnetic base type) mounted on the spindle drum and feeling against the spindle.

b) Check with bar gripped in the collet.

c) Use a short lever to exert pressure on the spindle, pushing the spindle the extent of the end float to obtain a reading.

d) The end float should be very gradually reduced by adjusting the locknut with short sharp taps on a wrench or a broad punch located in the slotted locknut. Remember, actual nut movement should be small, a 1/16in(1.5mm) turn on the outside of the nut will reduce the end float approximately 0.00017in(0.004mm). An end float of 0.0006 to 0.0008in(0.015 to 0.020mm) should be set for normal speeds.

e) The end float can be increased to 0.0008 to 0.0010in(0.020 to 0.025mm) for high speeds.

f) The cap screw in the slotted locknut should be tightened after each adjustment before reading the end flot and only slackened sufficiently to allow the nut to turn when adjusting.

g) After each adjustment, before reading the value of the end float, the spindles should be jogged to settle the rollers.

h) When over-adjustment reduces end float below 0.0006in(0.015mm) it is necessary, after turning the slotted locknut back, to separate the bearings a small amount by mallet blows on the rear (bar feed end) of the spindle. By this means it is possible to jolt the front bearing and the piston ring carrier away from the spindle shoulder so that mallet blows struck in the opposite direction re-seats the front bearing and piston ring carrier against the spindle shoulder. This procedure ensures that the correct end float reading is obtained and if not fully applied it may give a false reading which will increase under operating load as the bearings re-seat.

j) When adjusted satisfactorily run the machine at about 150 r.p.m. gradually increasing to the spindle speed required, observing the temperature at regular intervals on a thermometer placed in an end cap screw hole. Temperature should not exceed shop temperature, + 70 degrees F (21 degrees C) at approximately 400 r.p.m.

The following information applies if spindles and bearings are dismantled from the drum:-

a) Check that the oil feed and circulation holes are clear.

b) Assemble bearings on the spindle with the biggest bore for the adjustable bearing nearest to the locknut. This makes the end float adjustment easier.

c) Eccentric marks on the outer races to be in line and radially outwards.

d) Eccentric marks on the inner races to be in line.

e) The front bearing and piston ring carrier to be pressed hard against the spindle shoulder.

The tension on the collet is adjusted by means of the collet adjusting sleeve, and after fitting new collets, must always be tested by hand before running under power.

When adjusting the collet tension, extra clearance for the spanner (item No. 573X106) may be obtained by placing a spacing block (item No. 573X113) between the stop collar on the front guide rod and the bar feed slide, see fig.4.6. The spacing block should be placed into position when the bar feed slide withdraws.

The feed fingers are fitted to feed tubes carrying on their outer ends the bar feed bobbins mounted on anti-friction bearings. In order to remove the feed fingers it is first necessary to slide back the stock carriage tubes. These are held in the stock carriage indexing gear by clamps which must be slackened and turned clear to release the stock carriage tubes. By turning the plate on the rear of the centre stop the feed tubes may be removed from the machine complete.

Bar steady bushes are fitted in the end of the feed tubes and are retained by a screwed sleeve and slotted locknut.

Collets are of the draw back type and are opened and closed by a toggle mechanism on the rear end of the spindles and a spring compensator is included to accommodate small variations in bar size. The collet may be removed from the spindle by releasing the spring plunger and turning the collet adjusting sleeve until the collet is screwed clear.

The tension on the collet is adjusted by means of the collet adjusting sleeve, and after fitting new collets, must always be tested by hand before running under power.

When adjusting the collet tension, extra clearance for the spanner (item No. 573X106) may be obtained by placing a spacing block (item No. 573X113) between the stop collar on the front guide rod and the bar feed slide, see fig.4.7. The spacing block should be placed into position when the bar feed slide withdraws.

The feed fingers are fitted to feed tubes carrying on their outer ends the bar feed bobbins mounted on anti-friction bearings. In order to remove the feed fingers it is first necessary to slide back the stock carriage tubes. These are held in the stock carriage indexing gear by clamps which must be slackened and turned clear to release the stock carriage tubes. By turning the plate on the rear of the centre stop the feed tubes may be removed from the machine complete.

In order to extract the feed tube in station 1 it is necessary to withdraw the bar feed shoe. The machines are fitted with a screwed knob which can be pulled down to withdraw the shoe or turned to retain it in the withdrawn position. Bar steady bushes are fitted in the end of the feed tubes and are retained by a screwed sleeve and slotted locknut.

4.5 Workspindles 1.3/4"-8S (arranged for spindle stopping)

The spindle stopper version of the 1.3/4"-8 machine enables spindles to be stopped in stations and held in stations 3,4,5,6 and 7. All combinations of stopping and starting can be arranged between these stations.

Standard machines cannot be converted to a spindle stopper and provision must be made at an early stage of manufacture.

Fig. 4.8 shows the spindle drum assembly; each spindle gear is driven from the central gear and runs loosely on ball bearings when the multi -plate brake is engaged. The brake contains a series of preloaded cus hion springs which limit and maintain the brake torque and is sufficie nt to brake the spindles to a standstill.

The multi-plate drive clutch on each spindle is engaged by the axial thrust imparted by a row of balls, squeezed inwards against conical and flat faces by the clutch bobbin when it is moved by the cam operated clutch glut. The clutch is adjusted by turning the slotted nut from serration to serration on its right hand thread, the serrations being maintained in engagement by a series of clutch plate separation springs. The clutch is accessible for adjustment in the 8th station and an adjustment of one serration at a time can be made by a sharp hammer blow on the clutch punch 573X115. After adjustment the clutch must be checked using the hand lever 502X251 and a spring balance reading between 50 and 70lb (22.73 and 31.8 kgs) measured at the knob end of the lever should be maintained.

The clutch gluts are operated during indexing of the spindle drum by a series of cams secured in housings at the bar feed end of the drum housing. The cams may be selected to suit varying tooling requirements and are supplied to order. One cam housing is supplied as standard:- Cams are supplied to stop in stations ordered by the customer.

When fitting new cams handwind through index to ensure that the rollers pass freely all round the cam track.

Cross slide attachments and drives for use with spindle stopping machines are usually designed for a special and limited application to suit customer's components.

4.6 Dismantling (1.3/4"-8S Machine)

It is recommended that spindle removal be undertaken by Wickman Bennett Service Engineers who are fully trained and highly skilled in machine reconditioning.

A brief guide to the procedure is given below:-

The drive clutch and brake clutch gluts and operating shaft should be first removed, preferably in the 8th station. Unscrew the drive clutchglut retaining nut and the end nut at the brake glut (accessible through the drum housing). Withdraw the shaft through the gluts sufficiently to remove the key in the shaft at the brake glut end. Dismantle the shaft bearing at the drive glut end and withdraw the shaft, graduallu unscrewing the remaining nuts.

Remove the feed tube. Remove the cap screw and retaining washer from the end of the toggle carrier and withdraw the collet tube assembly. Remove the hexagon head screw (secured by a tab washer) from the toggle carrier and withdraw the toggle carrier assembly. Remove the spindle locknut and withdraw the drive clutch assembly. The shape shown as --- 2.3/16" --- , fitted over the operating sleeve will hold the ball thrust ring and retain the 24 operating balls.

Drive clutch plates can then be stipped. Unscrew the front bearing ad justing nut from the spindle. Dismantle the spindle nose thrower ring (where fitted) and the front cap covering the piston ring seal.

The spindle may then be withdrawn, stripping the drive gear and bearings, the rear bearing spacer, brake plates and operating sleeve and the front bearing nut and spacer, leaving in the drum the rear roller bearing and spacer and the brake spring assembly. The front bearings and spacers should withdraw with the spindle.

The rear roller bearing and its spacer are retained by an end cover and the brake housing which is clamped by cap screws through the drum.

Replace the spindle and its component assemblies in the reverse order to dismantling, ensuring correct order of replacement as the spindle is fed through the bearings. Other adjustments are as follows:-

Hold the glut shaft in the brake position by screw and collar in the end of the glut shaft and adjust the brake glut retaining nut to obtain 3/32in(2.38mm) compression of the brake springs.

The clutch is to be in neutral when tightening the spindle locknut which clamps the ball assembly.

4.7 Workspindles for the 50mm-8 Spindle Bar Automatic

The work spindles are supported at the front in a set of extra precision bearings comprising a parallel roller bearing nearset the spindle nose and a pair of preloaded angular contact bearings. An extra precision pair of deep groove ball journal bearings support the rear of the spindle.

The front bearings are protected against the ingress of coolant and swarf by a piston ring seal and labyrinth and a coolant thrower mounted on the spindle nose. The front bearing end cap is provided with a grease nipple so that the seal assembly can be filled with grease to exclude foreign matter. Inspection of the seal assembly can be made by removing the coolant thrower and the end cap.

The front and rear bearings are lubricated in the 5th and 6th stations by oil from a pressure header on the beam above the drum housing. Sight drip feeds mounted on the beam are provided for checking the flow. Spacing rings on the spindle assembly retain the lubricant to a suitable level and drilled passages in the drum allow internal oil flow around the front bearing assembly.

Collets are the draw back type and are opened and closed by a toggle m echanism on the rear end of the spindles and a spring compensator is i ncluded to accomodate small variations in bar size. The collet may be removed from the spindle by releasing the spring plunger and turning the collet adjusting sleeve until the collet is screwed clear.

The tension on the collet is adjusted by means of the collet adjusting sleeve, and after fiting new collets, must always be tested by hand before running under power.

When adjusting the collet tension, extra clearance for the spanner (item No 573X106) may be obtained by placing a spacing block (item No 573X113) between the stop collar on the front guide rod and the bar feed slide, see fig 4.7. The spacing block is provided in the tool kit and should be placed into position when the bar feed slide withdraws immediately before indexing commences.

The feed fingers are fitted to the feed tubes, carrying on their outer ends, the bar feed tube bobbins mounted on antifriction bearings. In order to remove the feed fingers it is first necessary to slide back the stock carriage tubes. by turning the plate on the rear of the centre stop the feed tubes may be removed from the machine complete. Bar steady bushes are fitted in the end of the feed tubes and are retained by a screwed sleeve and slotted locknut.

4.8 Collet Operation and Bar Feed

After the workpiece is cut off in 8th station the machine is indexed to the 1st station, the collet opened, bar stock fed out to the bar stop and the collet closed just before the advancing tools start cutting; see timing diagram fig. 4.44 in the 'Operator's Handbook'.

The collet operation mechanism consists of a cam operated slide moving on two round guide bars mounted between the drum housing and the end bracket.

A bonded fabric shoe carried in a slot in the slide engages in a groove in the collet sleeve on the work spindle. It is spring loaded so that if a collet sleeve indexes out of position the shoe will be depressed and rendered inoperative.

The collet slide is operated by a roller and barrel cam direct from the main camshaft and can be disengaged by loosening a pad bolt and pulling the roller carrier outwards clear of the cams. Adjustable nuts carried on a rod provide a stop for the operating slide and enable the mechanism to close the collets to a constant position, with either hand or cam operation. Fig.4.9 shows the correct adjustment for these nuts.

The bar feed mechanism is spring operated and controlled by a barrel cam on the main camshaft. The slide is mounted, as the collet operation slide, on the two guide bars and carries an aligning ring and a spring loaded shoe. The aligning ring encircles all the bar feed tubes and in the 1st station restrains the feed tube bobbin between the ring and the spring loaded shoe. The spring loaded motion of the slide and the shoe feeds the bar feed tube and the bar through the collet tube to the bar stop. On the return cam stroke the aligning ring returns the feed tube to a "ready to be fed" position and holds it there, together with the other bar feed tubes. Any endwise movement of the tubes is limited by the aligning ring and the adjustable centre stop, carried on a shaft extension on the stock carriage and centrally placed between all the spindles, see fig.4.9.

Two cams are needed to cover the bar feed stoke range; a 1/2in to 5in (12.7 to 127mm) cam is supplied as standard and a 5in to 10in (127 to 254mm) cam, 544Y106B is available to order.

For the 1.3/4"-8 machine only, two cams are available. The cam supplied as standard covers a range of 1/2in to 5in(12.7 to 127mm) and a 1.1/4in to 6.1/4in (32 to 159mm) cam, 502V258 is available to order.

On the 1.3/4"-8S machine only, the 1/2in to 5in (12.7 to 127mm) cam is supplied as standard, and a 1.1/4in to 6.1/4in (31.7 to 158.7mm) cam, No502 V 258 is supplied to order.

Collet tension and bar feed stoke adjustment is described under operating adjustments, in the 'Operator's Handbook'.

The machines are fitted with a limit switch operated by a rod and an adjustable clamp from the bar feed side. The function and the setting of this mechanism is covered under Auto-Stop Mechanism. See section 4.20.

4.9 Indexing and Drum Locking

The spindle drum is indexed anti-clockwise (looking on the collets) by gearing from the Geneva wheel. The mechanism is mounted at the rear of the machine on the bar feed end of the drum housing, and is shown diagrammatically on fig. 4.10. The four slot Geneva wheel and gear is driven by the passage through one of the slots of a roller carried on an arm mounted on the bar feed cam drum. During each fast motion cycle the drum is unlocked and indexed to the next station, 0.050in (1.27mm) past the final position. This allows a spring loaded latch in the spindle drumhousing to drop into position before the drum is clamped back against the latch and locator pads on the drum locking mechanism.

The latch, which is accessible through the front upper cover, should be adjusted with the latch sitting on the locator pad to give 1/32in to 1/16in (0.8 to 1.6mm) clearance to the nuts, as shown on fig.4.11.

The drum locking mechanism, accessible through the rear upper cover, is essentially a toggle mechanism arranged to lock the spindle very near to the dead centre position of the toggle.

The toggle pivots on a shaft with eccentric adjustment to obtain the correct clamping pressure and a stop screw in the drum housing is set 0.010in (0.25mm) clear of the toggle link to give the correct toggle off-set when locked. The following procedure should be followed to test for correct adjustment and should preferably be done when the spindle bearings have reached their normal running temperature:-

Place a tommy bar approximately 12in (304.8mm) long 5/8in (16mm) diameter, in a socket in the upper toggle link (a screwed cover on the top of the drum housing will have to be removed). Disconnect the pin in the operating lever and the long spring box rod situated near the end bracket, fig.4.11. Pull the tommy bar down slowly by hand as far as it will go. The toggle should just bind on the drum and if correct a slight resistance can be felt as the toggle grips when the tommy bar is slowly lifted. The high point of the eccentric is marked on the end of the shaft, visible from the collet end.

The toggle is operated by a link to a lever on the drum locking shaft which is connected to a cam lever by a pre-loaded spring box assembly, fig. 4.12. The long connecting rod should be adjusted to compress the spring 1/8in (3.2mm) when the drum is locked.

4.10 Feed Drive

The feed drive is transmitted by chain from the centre shaft to a hollow sleeve carrying a gear reduction to the first feed pick off gear shaft; gear "F" on the feed and speed charts. The mating gear "H" is mounted on one end of a shaft with gear "J" on the other end, meshing with gear "K" on the final pick off gear shaft. See fig. 4.13.

The final pick off gear shaft carries the feed overload slipping clutch to protect the drive during the feed portion of the cycle. The sideways disengaging action of the spring loaded clutch de-activates the electro-magnetic multi-plate feed clutch and the electro-magnetic multi-plate brake allowing the brake springs to "brake" the feed drive. The main motor then stops. Before the slipping clutch is re-engaged by sliding the driving dogs into mesh, the cause of the overload should be located and corrected. Access to the feed overload slipping clutch is through the cover carrying the speed and feed plate, fig.4.14.

After passing through the feed overload slipping clutch, the feed drive is transmitted by a pair of gears to the feed side of the feed motion-fast motion clutch.

A roller "freewheel" clutch is built into the gear on the feed motion-fast motion clutch shaft in order to maintain the drive whilst the clutch is in neutral when changing from fast to slow or slow to fast. The fast motion drive is taken from the constant speed pulley shaft by chain directly to the fast side of the feed motion-fast motion clutch.

The drive either fast motion or feed motion, then passes through the fast motion slipping clutch, to a pair of gears driving one side of the electro-magnetic multi-plate feed clutch on the final feed shaft. Adjacent to the feed clutch, mounted upon the final feed shaft is the chain drive sprocket for driving the upper longitudinal camshaft worm and wormwheel.

Bearing housing assemblies in the two outer walls and the inner wall of the attachment drive compartment of the main drive housing support the final feed drive shaft. In addition there is further bearing support between the inner wall and the motor drive end wall. The bearing housing at the motor drive end of the main drive housing also provides the means of mounting the electro-magnetic multi-plate brake which is outboard of the main drive housing.

Forward of the intermediate bearing support, the feed drive is transmitted through a dog clutch co-axially mounted upon and keyed to the final feed drive shaft. This dog clutch is spring loaded into engagement with the co-axial sleeve which provides journal support for, and to which is keyed the electro-magnetic feed clutch. The purpose of the dog clutch is to provide the means of disengaging the feed drive when hand winding the machine through its machining cycle.

The tensioning of the upper longitudinal camshaft worm chain drive is achieved by applying torque to an eccentric mounting for the chain tensioning sprocket. Access to the adjustment of the chain tensioning sprocket is from an external face of the main drive housing motor drive end. In order to adjust the chain tension loosen the hexagon clamping nut and apply a torsional load to the square provided on the eccentric mounting for the chain tensioning sprocket. On achieving the correct tension the hexagon clamping nut must be re-tightened.

The drive, either fast or feed, then passes through bevel pinions mounted on the front wall of the attachment drive compartment which drive the worm and wormwheel on the main camshaft, whose cams and mechanisms operate the cross slides, drum indexing and drum locking, collet opening and closing and bar feeding. The final feed shaft also carries the handwind gear which can be engaged by a handwind pinion when the feed and feed brake clutches are disengaged.

The feed-fast clutch is operated by a yoke and a lever from two adjustable dogs in the "T" slot on the upper wormwheel. The timing of the dogs can be set as required, normally shifting the clutch at the start of the feed period and at the end of dwell when the tools have finished cutting. A diagrammatic illustration of the feed motion and fast motion clutch control is shown at fig.4.15.

The electro-magnetic brake on the final feed shaft brakes the drive to camshafts when the electro-magnetic feed clutch is disengaged manually or by the auto stop control trip feed.

Instructions for adjusting mechanical multi-plate clutches are given on plates fixed to the machine. To increase the driving power of a clutch, rotate the spring ring around the adjusting nut and withdraw the locking plunger. Rotate the nut in the direction of the arrow stamped on the nut until the plunger can be engaged in the next hole in the locking plate. Do not adjust more than one hole at a time before testing the clutch. Replace the spring ring.

When testing the feed motion-fast motion clutches on their transmission shaft, the clutch actuating sleeve, when moved from its midway position should first move easily, build up resistance to a maximum just as the plates compress together and then ease slightly as the internal clutch toggles move over their high point. Set the minimum adjustment to obtain this feel without obtaining obvious clutch slip or overheating.

The electro-magnetic feed clutch on the final feed drive shaft is factory set and should require no further adjustment.

The electro-magnetic brake on the final feed shaft should be adjusted as follows:- Remove the cover to obtain access to the brake. Engergise the brake. Refer to the diagram mounted on the cover. Release the grub screw (A) in the centring ring (B). Introduce a resetting key (kept in a slot inside the cover) into a radial groove (C) in the centring nut (D) and turn the nut until the key can be smoothly withdrawn. Check the air gap with the brake de-energised using a 1.2mm(0.048in) feeler gauge. Reclamp the grub screw (A) when the correct gap is obtained.

Emergency brake release:- In order to release the brake for handwinding when the electric power is not available, remove two knurled plugs in the cover and remove metric screws from the tapped holes above the instruction plate. Insert screws through the cover holes into holes in the brake body and turn the screws clockwise as far as possible to release the brake. Remove the screws, replace metric screws and plugs before connecting power to the machine.

Slipping Clutches:- These clutches are assembled with the minimum number of springs and plungers necessary to transmit the torque. Spare plungers, springs and screwed plugs are supplied in the equipment kit and can be fitted when required. It is recommended that the number of plungers in use is kept to a minimum to ensure that the clutches will disengage when necessary. Fit extra plungers, etc, in pairs equally spaced around the clutch body.

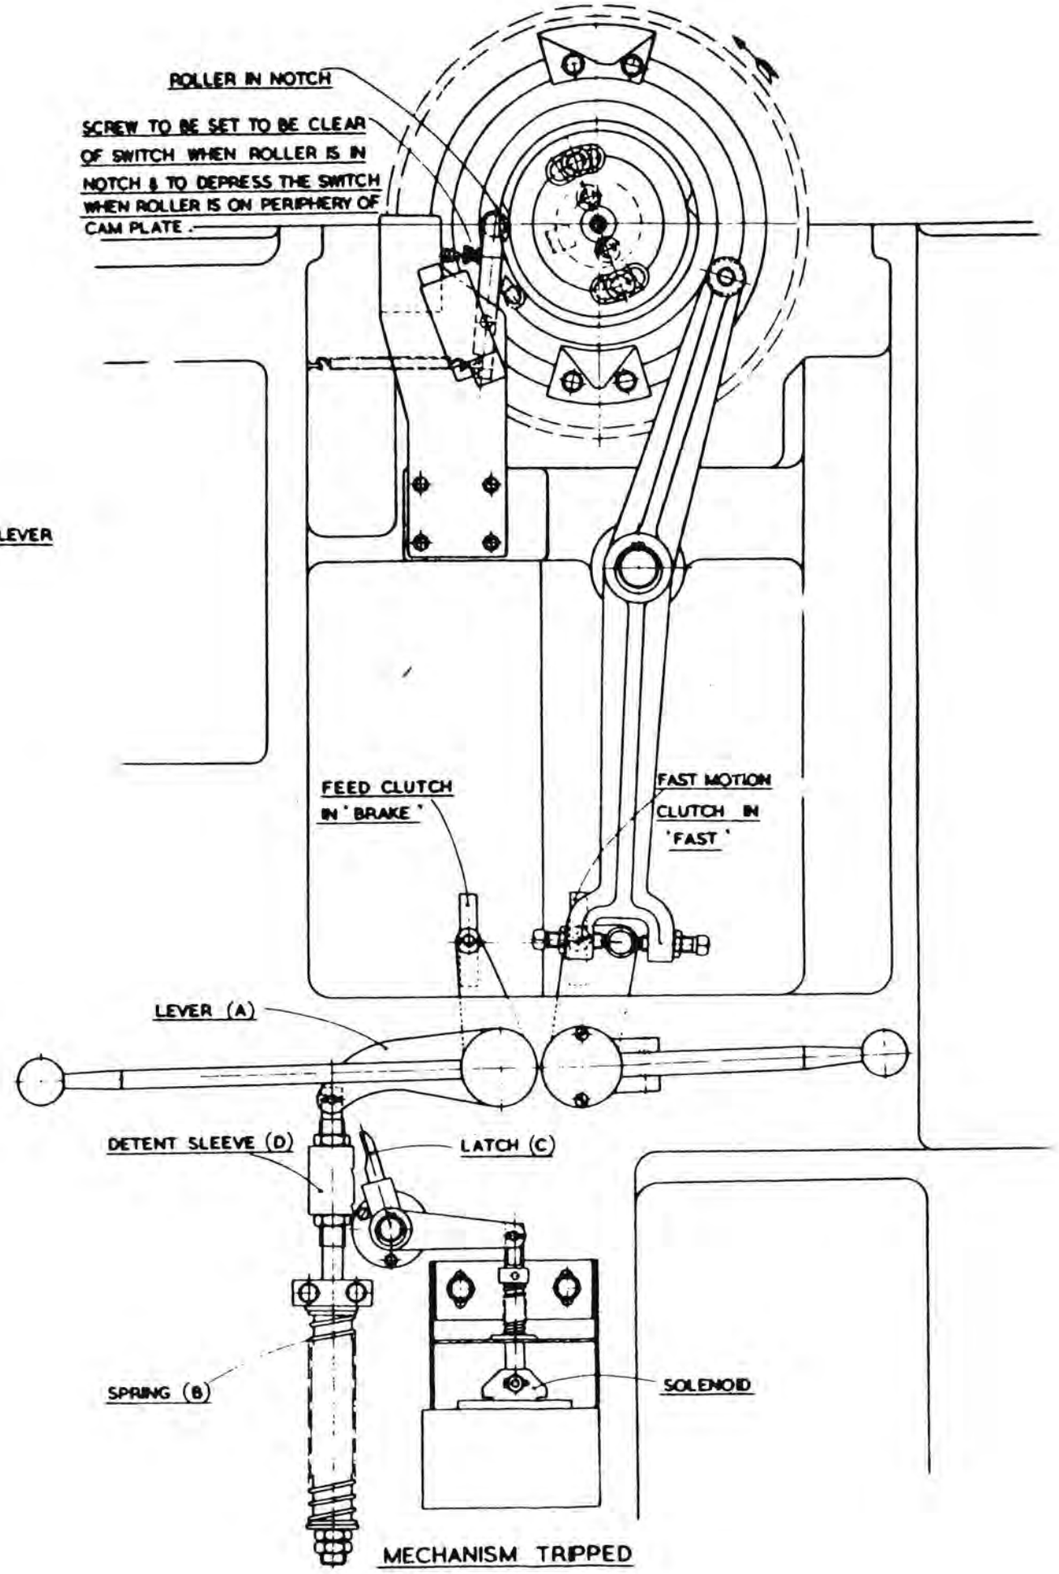
MECHANISM SET



MECHANISM TRIPPED

4.11 The Main Camshaft

The main camshaft extends from the wormwheel in the main drive housing, passing through the drum housing to the stock carriage end bracket of the machine. The camshaft is supported in plain bearings in the main drive housing attachment drive compartment walls and the walls of the drum housing and its tail end is supported by a ball bearing assembly in the stock carriage end bracket of the machine. It carries the cross slide feed and approach stroke cams, bar stop, bar feed and collet operating cams, spindle drum locking cams, the Geneva arm and roller and the index clutch.

A cam drum is fitted in the main drive housing to carry cams for special end working attachments when these are required and a 2in (50.8mm) bore is provided in both walls of the housing to carry a shaft upon which the necessary cam operating levers can be pivoted.

An auxiliary cam disc is provided in the drum housing to accommodate special cams for varying independently the movements of individual cross slides or cross slide attachments when required. A timing hole is provided in this auxiliary cam disc which lines up with a corresponding hole in the drum housing wall when the camshaft is at 0 degree timing angle.

The keyway in the shaft and the vee grooves across the diameter of the auxiliary cam disc and the spare cam drum, are horizontal and to the front of the machine at 0 degree timing angle. At this point the Geneva roller is just entering the Geneva wheel. See figs. 4.10 and 4.16.

Index clutch operation.

The bar feed cam drum is driven by a dog clutch spring loaded into engagement and carried on the main cam shaft. Lifting the index clutch lever until the plunger handle locates in a hole in an adjacent bracket, withdraws the clutch teeth and renders inoperative bar feed, collet operation, drum indexing and the drum locking mechanisms. An interlock latch is fitted so that the clutch cannot be disengaged during the indexing of the drum. See figs.4.10 and 4.16.

DEVELOPMENT OF SPARE CAM DRUM 14

4.12 Upper Camshaft

The upper camshaft is transversely mounted across the top of the main drive housing. It carries disc cams which operate the centre tool block and the longitudinal slides. Cam carriers are also fitted for cams to operate the 3rd,4th, 7th and 8th station longitudinal motions.

The cam dogs controlling the fast motion clutch are mounted in a circular tee slot machined in the face of the worm-wheel; a timing dial is provided at the front and rear ends of the upper camshaft.

The worm-wheel drives the upper camshaft through serrations on the face of the wormwheel and a serrated plate engaging a tenon slot in the upper camshaft. By releasing the centre screw and the two outer screws this serrated plate may be disengaged from the worm-wheel. By hand winding the machine, the lower camshaft and the upper worm-wheel may be turned while the upper camshaft remains stationary, thus enabling the timing of the main camshaft and the upper camshaft to be altered or corrected as required. It is vitally important that the serrations engage properly and that the screws are fully tightened after altering the timing.

A vee groove is cut across the periphery of the cam discs and is vertically above the centre of the camshaft at 0 degree timing angle. See figs. 4.17 and 4.18.

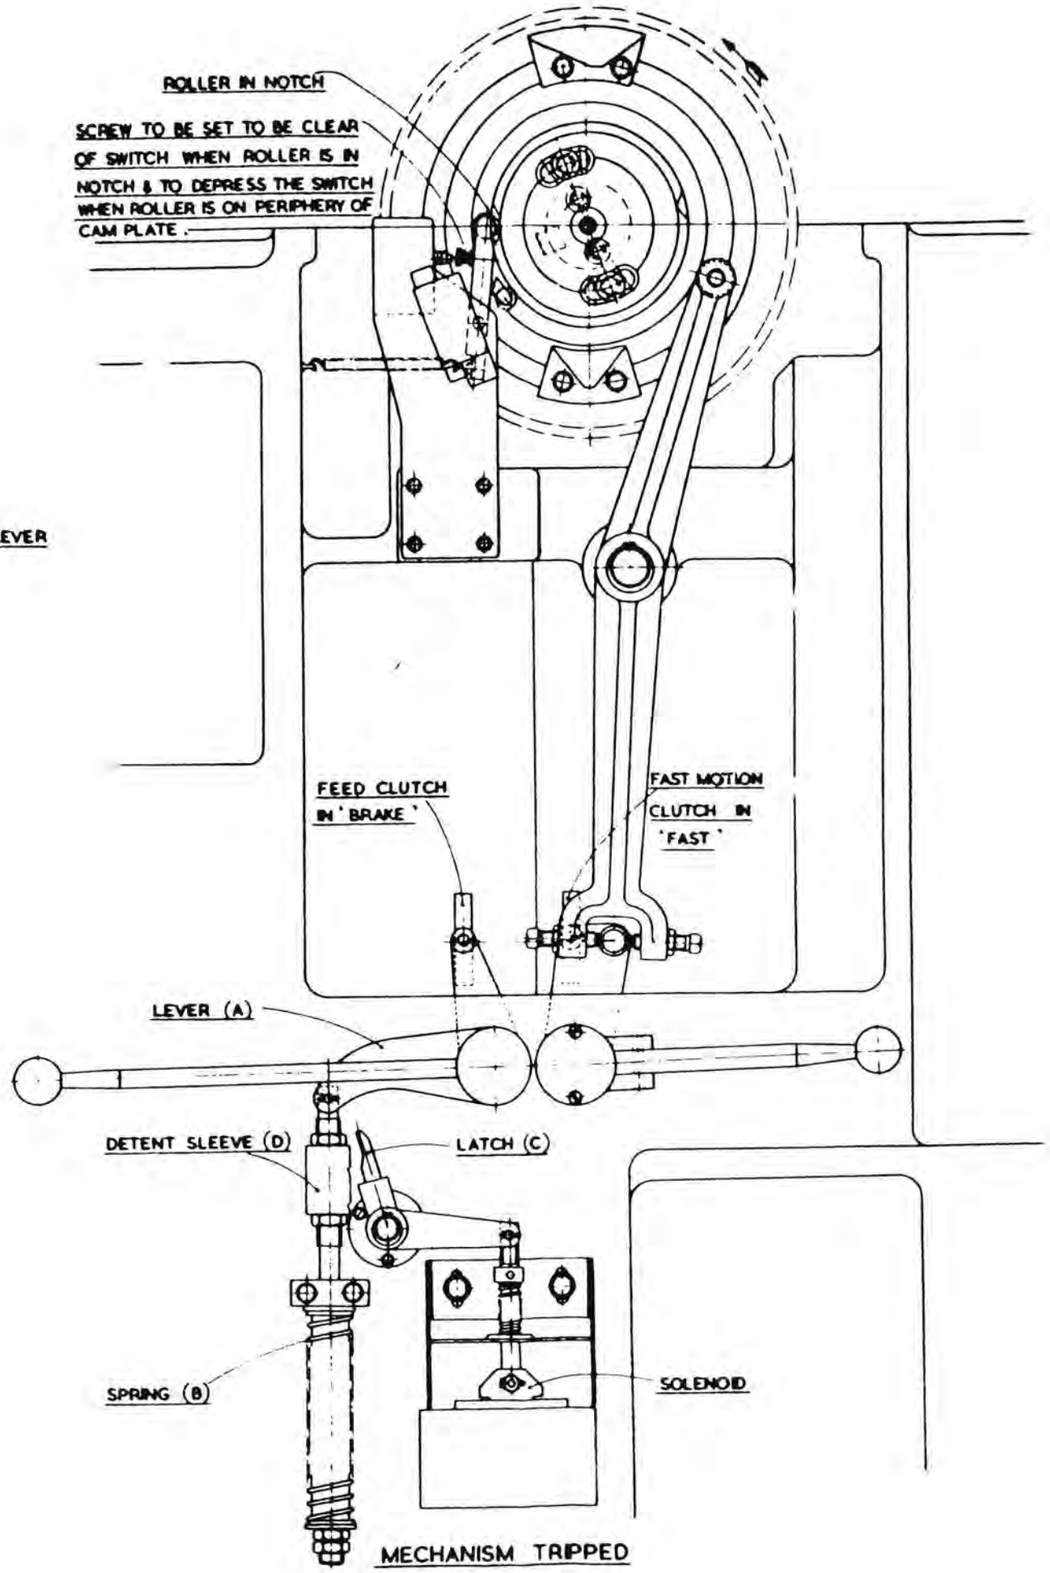
MECHANISM SET



MECHANISM TRIPPED

4.13 Centre Tool Block and Longitudinal Slides Operating Mechanism

The mechanism derives its motion from cams on the upper camshaft, the three slides being operated by a series of racks and levers to give each slide a constant fast approach stroke and an infinitely variable feed stroke; centre block 0 to 5in (0 to 127mm), independent longitudinal slides 0in to 5.5/8in (0 to 143mm). A sliding block with provision for three sets of pinions and slideways for racks is carried in guides on the top of the main drive housing and when cam operated, imparts the fast motion stroke to the three slides. The block is locked in its forward position and three separate quadrant levers are cam operated to provide the feed motion through the racks and pinions to the slides.

At the end of the fast motion stroke the sliding block lockbolt enters a tapered setting on the block; if the seating is not directly under the lockbolt the block will be moved and consequently double the movement on the toolslides. The setting is shown on figure 4.19.Unless dismantled or cam wear has occurred, adjustment should not normally be necessary. The adjusting procedure is as follows:-

Stop the machine at the end of the fast approach stroke with the lockbolt "IN" and remove the sheet metal covers. Dismantle the lockbolt operating lever by removing its eccentric pivot pin.

Release the spring load on the lockbolt by unscrewing the retaining cap. The spring load is approximately 60lb. (27Kgf) and the cap can be held down by an assistant if the two opposing screws are first removed.

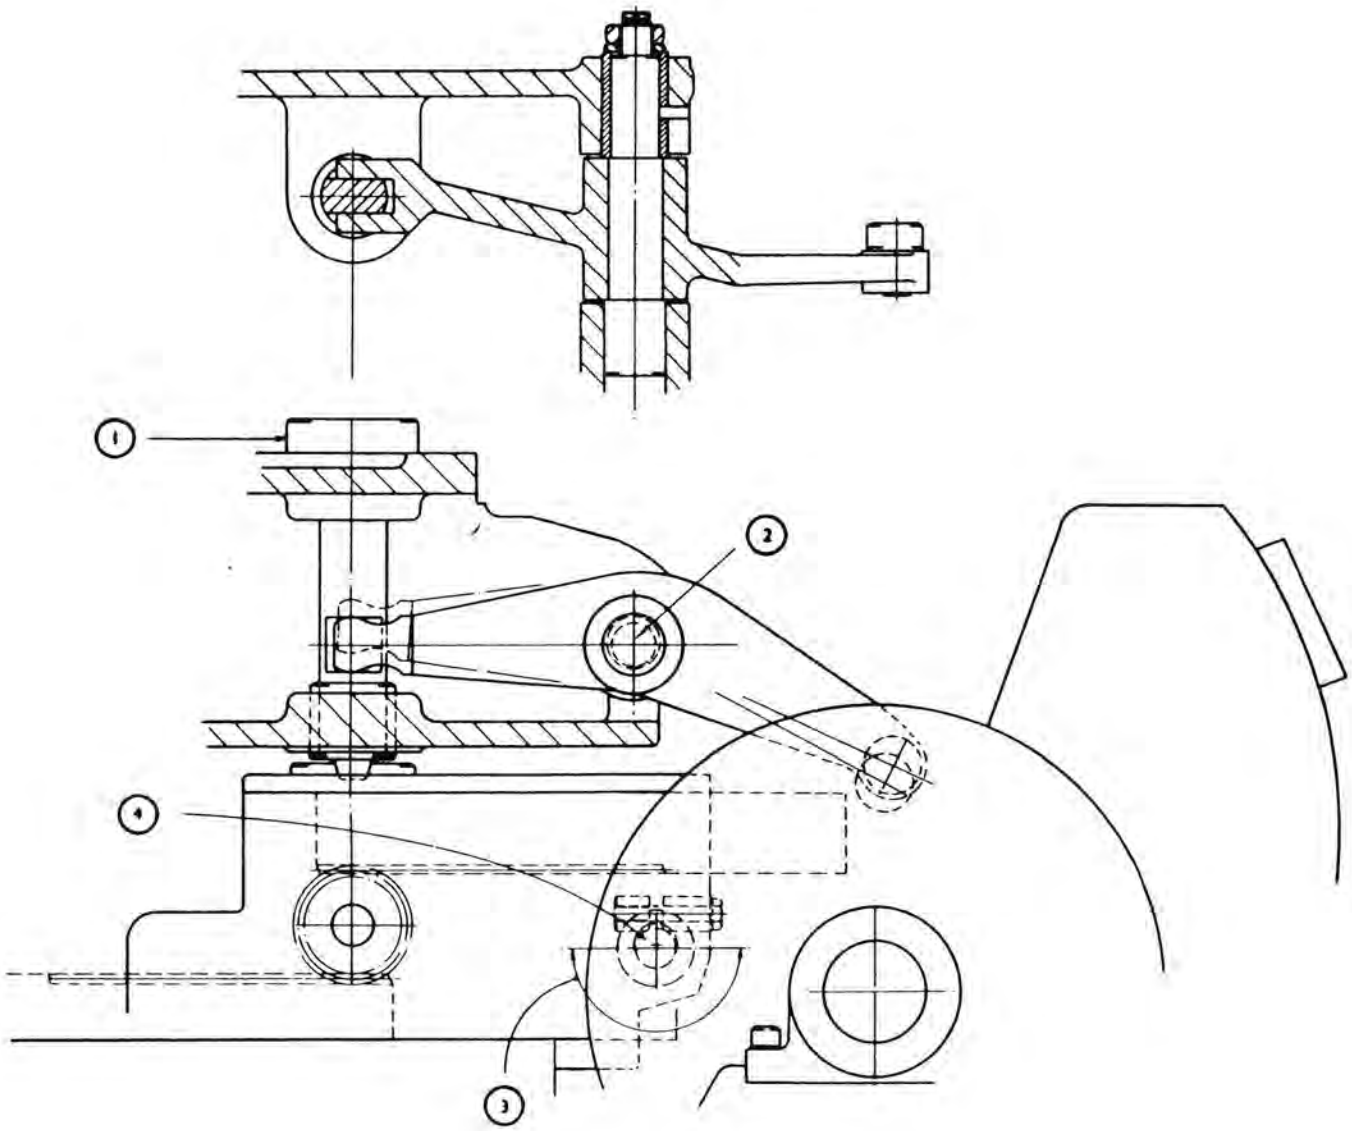
Fit a long B.S.F. fine thread bolt or stud in the thread in the lockbolt to enable it to be pulled clear of its seating. With the lock bolt withdrawn handwind the machine backwards until the sliding block starts to retract, then carefully forwards until the block is just at the maximum forward position on the fast motion cam.

The block should then be moved with gentle blows from a mallet until a 0.003in (0.076mm) feeler can be trapped between the outer part of the cam and the roller. In this position the lockbolt should fit exactly in the tapered seating without moving the sliding block setting. In order to reset the sliding block, release the pad bolt holding the cam roller pin and turn the pin by the hexagonal end to obtain the exact seating condition. The eccentricity must be kept in the lower half as shown on fig.4.18.

After making the adjustment, the pad bolt nut must be tightened to a maximum to prevent pin movement.

Re-assemble the lockbolt operating lever and adjust its eccentric fulcrum by the squared end to just nip the lockbolt down in the seating with the roller on the inner cam. See figs. 4.18 and 4.19.

Fig.4.19



4.14 Changing Feed Stroke

This is dealt with in the Operator's Handbook.

4.15 Changing Fast Motion Approach Stroke

Two alternative cams are available for 3.1/2in (88.9mm) and 5in(127mm) stroke. Changing involves the removal of the upper camshaft.

Auxiliary motions are available for the 3rd, 4th, 7th and 8th stations on the eight spindle machines, see Attachments section in the Operator s Handbook.

4.16 Centre Block and Longitudinal Slides

The centre tool block, fitted with bushes and scraper rings, slides on the centre guide which indexes with the spindle drum. Torque loads are taken against guide faces in the beam by a guide block on top of the guide arm, adjustment for wear being provided by a gib strip. When adjusting the gib strip carefully check the adjustment throughout the travel as wear will tend to occur on the portion covered by short strokes. Access is through the covers on top of the beam, see fig. 4.20.

Oil is fed from drip points in the beam to a strainer on the guide block and down a pipe to the reservoir between the bushes in the centre tool block. Drain and filler plugs are provided for periodical draining and flushing out.

The centre tool block is pushed by a double link from the lower centre rack and no endwise adjustment is provided. The stop rod is provided to control length accuracy. Stop nuts should be slackened off well clear before adjusting slide strokes as the final position of the tool block is not constant for all strokes.

The faces and the tenon slots of the tool block are ground to close tolerances and standard toolholders and attachments may be fitted to any face without selection for height or centrality.

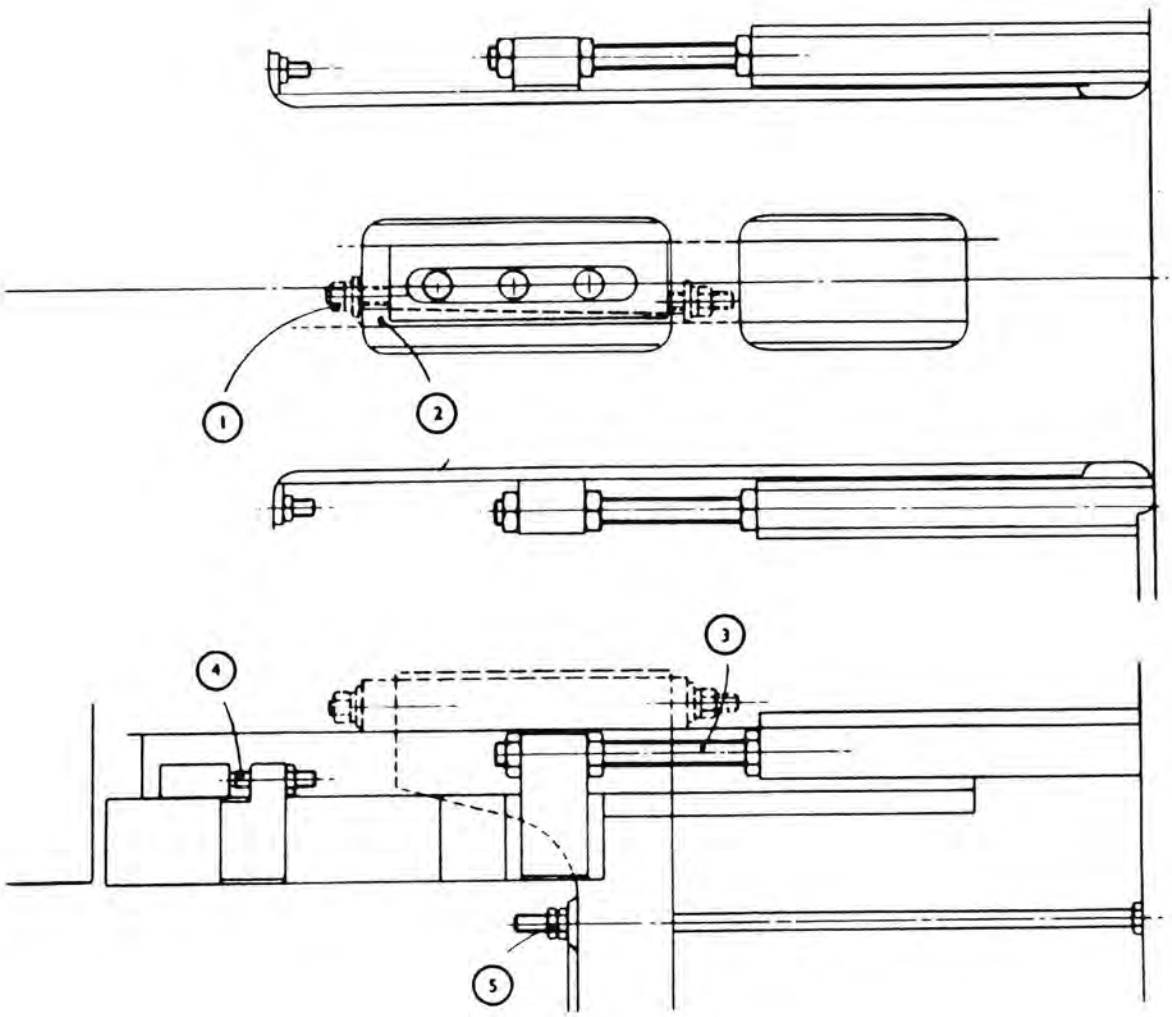
The longitudinal slides are mounted on vee guides fitted on the beam which are accurately adjusted for alignment and centrality by a tenon block secured to each end of the vee guide. Screws in the beam clamp the blocks to one side of a beam slot.

Tapered gib strips are provided and the headed screws at each end of the slide should be adjusted with the tool (573X108) supplied in the tool kit.

Each slide is pushed by a rod screwed into the pusher bar and is adjustable for position 3.1/2in(88.9mm) by means of nuts on the rod. A spacer between the nuts is slightly wider than the bracket on the slide to allow for slight misalignment of the pusher rod.

As with the centre tool block, stops should be well clear before adjusting strokes.

Fig.4.20



4.17 Cross Slide Operation Mechanism

The mechanism is situated in the drum housing and consists of a series of levers and pivoted links operating upon gear quadrants and racks to give the slides a two part motion of fast approach and withdrawal and a slow feed similar to the longitudinal slides.

The fast approach is by cam operated toggles, actuating two heavy "rocking" levers through a short arc. A cam on the main camshaft extends a toggle, swinging the front lever pivot on two stop screws in the drum housing floor. A second cam on the main camshaft imparts a similar motion to the rear rocking lever. Adjustment to the stop screws should only be required after a long period of service, fig. 4.21 illustrates and explains the adjustment.

Clamped into the tee slots on the rocking levers are adjustable link pivots with links extending to suitable levers on the cross slide operating shafts. An extension on each rocking lever carries a cam roller controlled by the feed motion cams on the main camshaft.

Figure 4.22 shows the adjustment provided for meshing the gear quadrants and racks on the lower cross slides.

All cross slides have independent feed stroke setting, adjustable by sliding the appropriate link pivot along the rocking lever tee slot to a setting indicated by a pointer on a scale. See also "Operating Adjustments" in the Operator's Handbook.

The upper cross slides have a double range of feed strokes, the "long" range being equal to twice the scale reading. The change-over is obtained by transferring the upper link pivot connection from the outer hole "B" to an inner hole "A" in the operating lever. It is necessary to remove a retaining circlip on the pivot pin and to restrain the slide spring load with a pressure on the top of the operating lever to withdraw the pin.

Changing intermediate cross slide feed stroke range

The changeover, as on the upper slides, is by transferring the link pivot from an outer hole "B" in the operating lever to an inner hole "A".

Access to the operating lever is by removing the screwed cover on the side of the drum housing.

Set the maximum stroke on the rocking lever scale and with the slides in the withdrawn position adjust the micrometer head to bring the slides to the maximum back position. A hexagon headed bolt clamps the link pivot to the operating lever, the bolt passing through the lever into the threaded pivot. Unscrew and withdraw the bolt and slide the link and pivot along a slot in the lever to the alternative hole setting. It is necessary to restrain the slide return spring with pressure on the operating lever or the end of the slide. Replace the clamp bolt and set the feed stroke and the slide position as required.

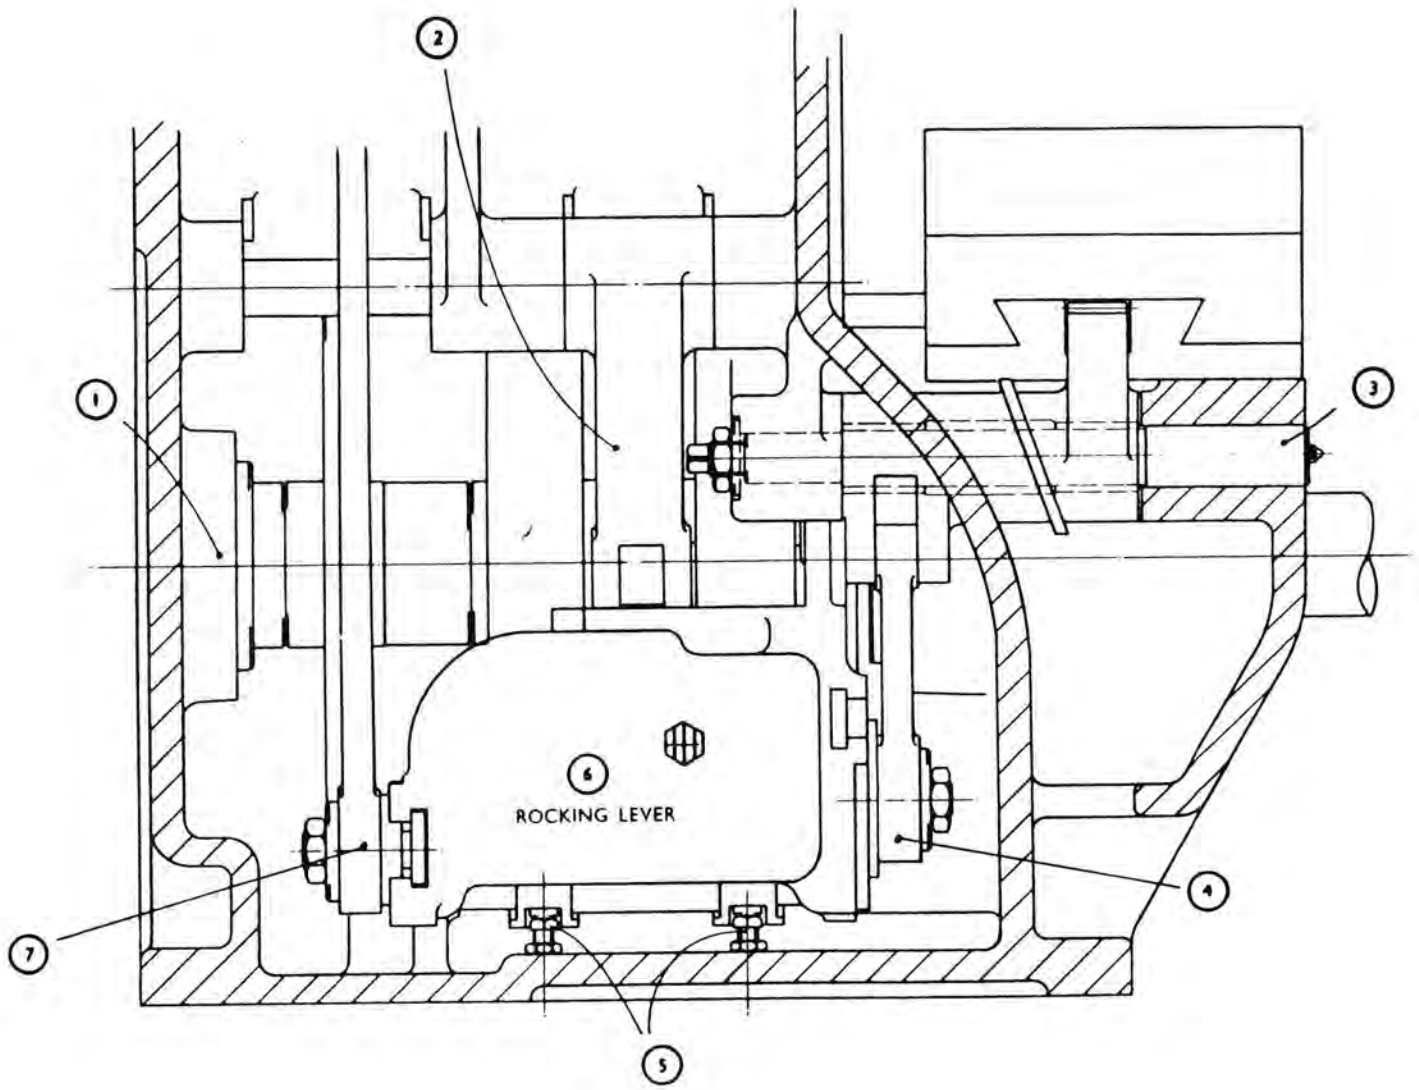
Fig.4.22



4.18 Bar Stop and Operation

Operating adjustments are described in the "Operator's Handbook". The bar stop movement is derived from two cams on the main camshaft, operating on a lever fitted with two cam rollers. One cam and roller swings the bar stop into position and the other returns the bar stop after bar feeding. The lever is connected to an upper operating lever on the bar stop shaft by a spring box link, the bar stop shaft being carried on brackets between the housings. The mechanism is protected by a front and rear cover secured to the main drive housing attachment face. Normal operation swings the bar stop up from between the lower cross slides to the first station spindle centre, the upper operating lever contacting an adjustable stop and compresssing the spring box 1/8in (3.17m).

The bar stop can be arranged to swing over the first station slide by fitting the upper spring box pivot connection and operating lever on the opposite side of the bar stop shaft. The front cover should be removed, the adjustable stop in the support bracket released and withdrawn, and the lock-nut on the top of the spring box link unscrewed. The spring link can then be disconnected from the lever by turning the hexagon on the spring shaft at the top of the tube clockwise. This should detach the operating arm which together with the shaft, can be turned over and reconnected to the spring box. The bar stop and the bar stop arm should then be re-aligned to the spindle and the dead stop fitted in the location provided and adjusted to compress the spring box 1/8in (3.17mm). The bar stop is formed with a shaft end which is clamped in the bar stop arm. A square headed screw acts on the shaft end for fine adjustment.

4.19 Automatic Stop Mechanism

The automatic stop system covers two sets of circumstances:-

(A) Those circumstances where it is necessary to stop the feed and spindle rotation at the end of the cycle. Such circumstances are:-

1.Bar exhaustion.
2.Incorrect lubrication pressure or failure.
3.Threading attachment fails to return.
4.Safeguarding certain special attachments.
5.Pneumatic or hydraulic pressure failure where applicable and automatic stop at end of cycle is permissable.

(B) Those circumstances where it is necessary to stop the feed and spindle rotation immediately in order to safeguard operating personnel and equipment such as:-

1.Slipping clutches thrown out of engagement.
2.Pneumatic or hydraulic pressure failure when this type of equipment is used.
3.All safety aspects which demand instant termination of feed and spindle rotation.

The chart shown at fig. 4.23 is a guide to the normal reasons for the machine stopping either at the end of a cycle or immediately.

The automatic stop action is created by a switch, the two timed stops being:-

(a) After drum indexing with the collet open and the bar feed slide forward.

(b) With the slides withdrawn clear of the components just before indexing.

In order to stop as outlined in (a), a cam timing switch, see fig. 4.18 is operated by the cam plate on the upper camshaft in conjunction with the switch operated by the forward additional feed of the bar feed slide, and with the three position selector switch marked; SET UP, TRIP and RUN, and mounted in the front pendant control panel, set in the RUN position.

During bar feeding, the forward motion of the bar feed slide is stopped approximately 1/2in (12.7mm) short of its available travel by the bar contacting the bar stop. When the bar is so short that the bar feed slide is able to move an extra 1/4in (6.35mm), a switch adjacent to the bar feed slide is operated by the slide to prepare a circuit, such that with the operation of the cam timing switch on the upper camshaftbeing activated, the electro-magnetic feed clutch and brake is de-energised stopping the feed. It also causes the main motor contactor to open and stop the main motor, see the wiring diagrams for a full explanation of these circuits. A similar use of the cam timing switch, combined with pressure switches in lubrication, pneumatic or hydraulic circuits if employed, de-energise the electro-magnetic feed clutch and brake if a failure occurs in such systems.

In order to stop as outlined in (b), an extra cam timed threading return switch, mounted parallel to the cam timing switch and activated by the cam on the upper camshaft, will de-energise the electro-magnetic feed clutch and brake should the threading attachment fail to retract and activate the threading return switch mounted adjacent to the main drive housing attachment face. As the panel relay is not affected, the motor and machine spindles are left running. See wiring diagrams for a full explanation of these circuits.

In addition to stopping as outlined in (a) and (b), the operation of a switch adjacent to the feed overload clutch will directly de-energise the electro-magnetic feed clutch and brake, stopping the feed instantl y during any part of the machine cycle. Other switches can also be em ployed to stop the feed instantly for safety purposes on special attac hments etc. The setting of the overload clutch is shown on fig. 4.24.

4.20 Coolant

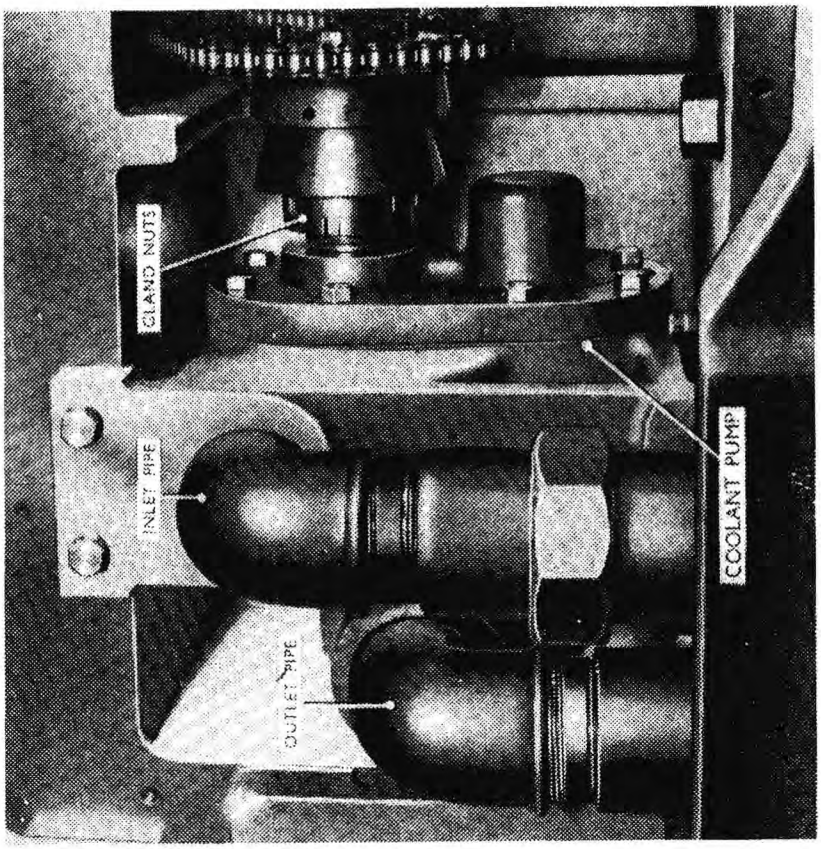
The coolant is supplied from the machine tray by a gear pump, chain driven from the constant speed shaft. Chain adjustment is described on page..... An adjustable gland is fitted to the driving shaft to prevent leakage and this should be adjusted as lightly as possible to prevent overheating and pump seizure. A relief valve is fitted in the pipe system to return excess coolant to the tray. Coolant taps are arranged adjacent to the lower cross slides and on headers on each side of the machine beam and additional plugged holes are provided in the headers.

The chain drive should be removed when the machine is to be run without coolant in the machine tray.

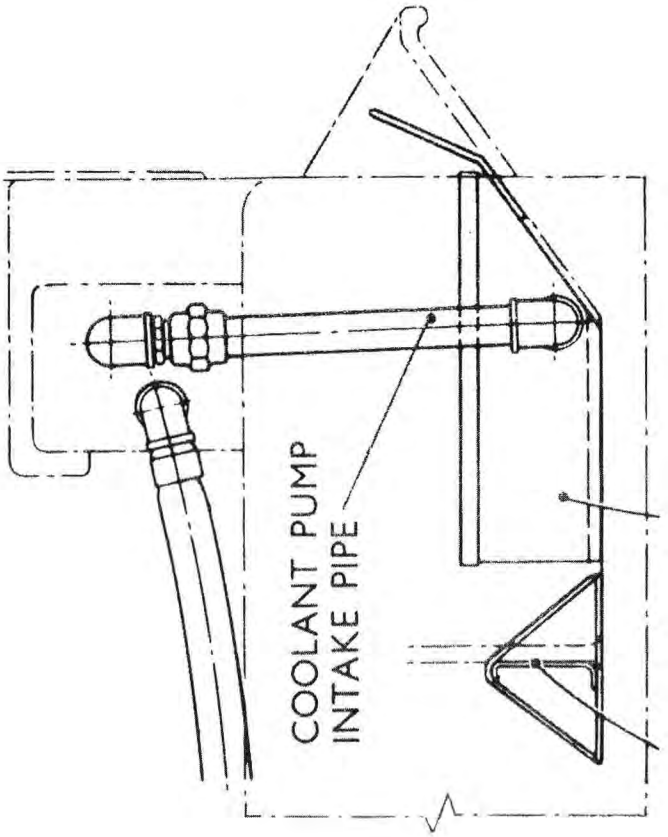
The strainer box and weir must be in position at all times to prevent swarf entering the supply pipe. The strainer is fitted with a loose lid and should be inspected and cleaned at regular intervals, see fig. 4.25.

Machines constantly working on operations requiring oil fed cutting tools can be equipped to special order with an additional high pressure pump and a filtration system, either of the magnetic drum type or one of the centrifugal type dependent upon the material to be machined and the type of coolant to be used. For these systems, pipe work is installed to draw the supply from a strainer in the machine tray or from a separately piped supply. Filtration systems using proprietary items should be cleaned and serviced as directed by the maker's instructions.

Fig.4.25



Coolant Pump



Coolant Pump

4.21 Stock Carriage

The two main parts, the stand and the tube assembly, are erected and aligned as described in the Operator's Handbook. The tube assembly has a central tube to which are secured two tube carriers to space and guide the stock tubes. The rear carrier is supported on rollers in the stock carriage stand.

At the machine end, the front carrier is gear driven during indexing by a pinion from the drum indexing mechanism and must be correctly meshed to the marks on the gears. The stock tubes are located by a by a flanged sleeve secured to each tube and clamped in pairs to the front carrier.

The tubes should be handled carefully; bent or distorted tubes will make it more difficult to slide the tubes through the carriers.

Convoluted spring linings to provide resilient support for the bar stock are not normally required, but are available to order. Where supplied, springs should be kept well lubricated with soft grease.

4.22 Swarf Conveyor

The swarf conveyor is fitted as an optional extra, but conduit and wiring is normally fitted to all machines, from the panel terminals to a junction box on the beam to simplify later installation. A conveyor unit supplied separately includes control buttons and contactor for panel mounting and conduit, wiring and a "Niphon" socket for installation to the machine.

The screw type conveyor is driven by a 1/4 h.p. motor and a reduction gear box, controlled by push buttons on the pendant control panel door.

A shear pin in the coupling adjacent to the motor gear box provides overload protection in addition to that provided by thermal trips in the motor starter. Spare silver steel shear pins are supplied in a container clipped to the side of the conveyor. Before replacing a shear pin, the cause of the overload should be found and removed. Holes are provided in the end of the conveyor screw so that it can be turned by hand.

Steel chutes are fitted in the tray between the housings to guide the swarf into the conveyor. When the conveyor is fitted the coolant intake pipe extends to the drum housing end of the machine, as illustrated on fig. 4.26. The main overflow of coolant is discharged into a basket under the main drive housing collecting the fine particles of swarf held in suspension in the coolant. The basket is accessible from the end of the machine and should be emptied at regular intervals.

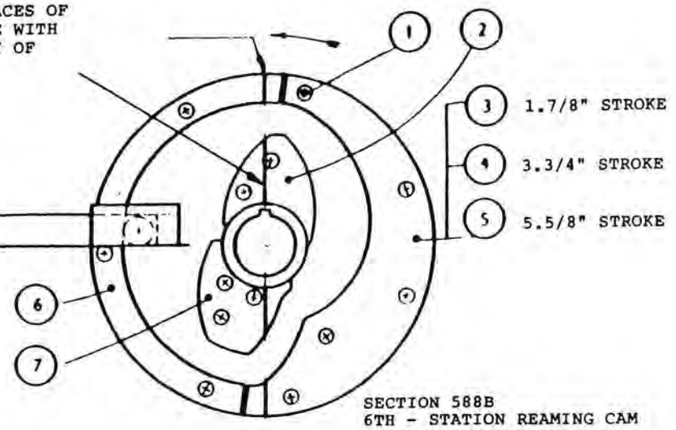
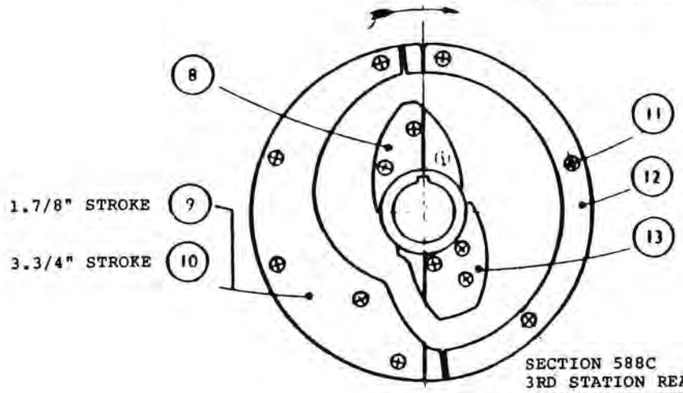
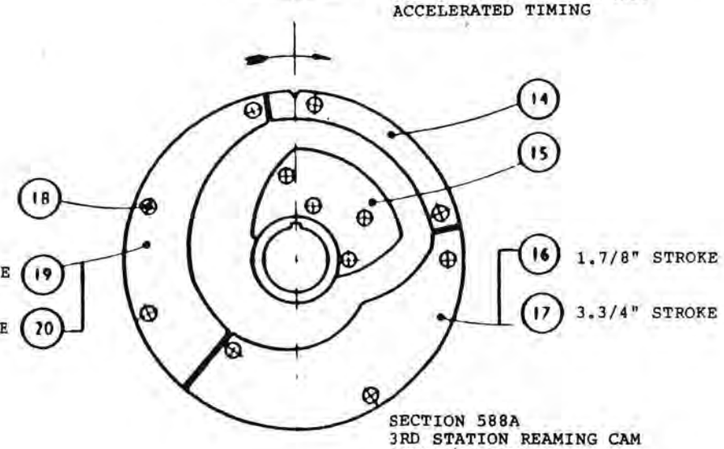
LINES MARKED ON FACES OF CAMS TO BE IN LINE WITH NOTCH IN PERIPHERY OF CAM CARRIER



SECTION 588B
6TH - STATION REAMING CAM
ACCELERATED TIMING



SECTION 588C
3RD STATION REAMING CAM
ACCELERATED TIMING



SECTION 588A
3RD STATION REAMING CAM
STANDARD TIMING

REAMING

TO OBTAIN FEED PER REV

STANDARD TIMING CAMS (STAT. 3 ONLY)
FEED PER REF.
IS THE SAME AS SHOWN ON SPEED AND FEED CHART FOR THE PARTICULAR STROKE IN USE

ACCELERATED TIMING CAMS (STAT. 3 & 6)
MULTIPLY ACTUAL STROKE BY TWO AND FIND FEED PER REV. FOR THIS STROKE FROM SPEED AND FEED CHART

THREADING USING REAMING CAMS
(DIEHEAD OR COLLAPSING TAPS ONLY)
TO OBTAIN STROKE REQUIRED

STANDARD TIMING CAM (STAT. 3 ONLY)

STROKE REQUIRED = AVAILABLE CUTTING REV.

TP: - THREADING ON RATIO

ACCELERATED TIMING CAM (STAT. 3 & 6)

STROKE REQUIRED = AVAILABLE CUTTING REVS.

2 X T.P.I. = THREADING ON RATIO

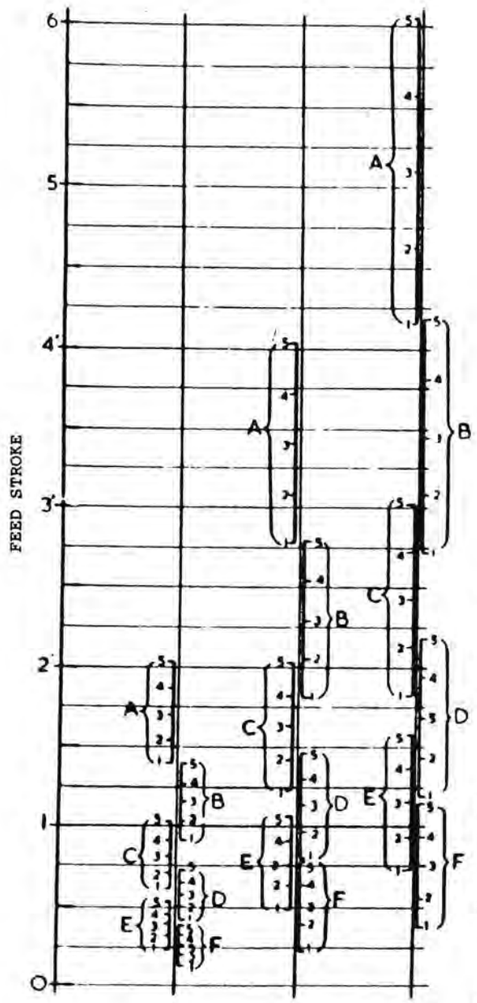
TO READ CHART

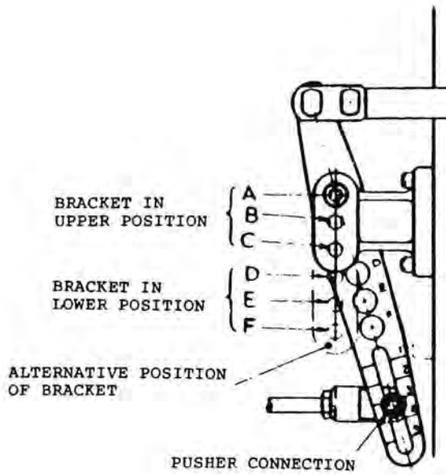
1 - ON FEED STROKE SCALE ON LEFT MARK THE FEED STROKE REQUIRED
2 - DRAW HORIZONTAL - LINE ACROSS TO VERTICAL LINE REPRESENTING CAM FITTED (1.7/8", 3.3/4", 5.5.8") STROKE
3 - WHERE THE VERTICAL LINE GIVES THE PIVOT POSITION (AB -ECT) AND THE RELATIVE POSITION OF THE PUSHER CONNECTION WITH THE GRADUATIONS ON THE LOWER END OF THE LEVER (12 ECT)

588Y2A

THREADING CAMS, STATIONS 3 AND 6 - DRAWING NO. 587 Y 3A

INDEX NO.	PART NO.	TITLE
1	155/0814	1/2" B.S.F. socket Head Cap Screw 7/8" long
2	587B.Y.104	Inner Guard Cam
3	587B.Y.108	Threading Cam
4	588B.Y.105	Guard Cam
5	587B.Y.106	Return Cam
6	588C.Y.104	Inner Guard Cam, Station 3
7	587C.Y.108	Threading Cam
8	155/0814	1/2" B.S.F. Socket Head Cap Screw 7/8" long
9	587C.Y.106	Return Cam
10	588B.Y.105	Guard Cam
11	587A.Y.105	Guard Cam
12	587A.Y.106	Return Cam
13	587A.Y.107	Return Guard Cam
14	587A.Y.108	Threading Cam
15	155/0814	1/2" B.S.F. Socket Head Cap Screw 7/8" long
16	87A.Y.103	Drop Back Cam





TO OBTAIN STROKE REQUIRED:-

USE THE FOLLOWING FORMULAE TO OBTAIN STROKE REQ. WITH 3RD & 6TH POS. THREADING CAMS

STROKE REQUIRED = AVAILABLE CUTTING REVS.

4 X T.P.I. X THREADING RATION 'ON'

TO FIND STROKE SETTING:

1: ON FEED STROKE SCALE ON LEFT MARK FEED STROKE REQUIRED (CALCULATED AS ABOVE)
2: DRAW A HORIZONTAL LINE ACROSS TO BRACKETED COLUMN
3: WHERE THE HORIZONTAL LINE CUTS THE BRACKETS GIVES THE PIVOT POSITION (A,B, ECT) C THE RELATIVE POSITION OF THE PUSHER CONNECTION WITH THE GRADUATIONS ON THE LOWER END OF THE LEVER (1, 2, ECT)

APPROACH STROKE = 375 x FEED STROKE
